There actually are benefits to soldering the shield all around the shell. If you don't, an impedance increase occurs where the field is allowed to escape the region between the center conductor and shield. This isn't a problem in most amateur applications, and likely not a problem in other applications, either, if a non-constant impedance connector is being used in the first place. Possibly more important, though, is that you've allowed a path for common mode current, that is, current on the outside of the shield. In addition, the increased impedance of the desired current path encourages the flow of common mode current. The main effects of the common mode current are radiation from the coax when transmitting, and pickup of local noise when receiving. These might or might not present a problem, depending on individual circumstances.

While I am on a roll let me compare a Faraday cage with what is known
about radiators
Aperture in the books is a relative measure of gain. In otgher words
the shere thatr encircles a radiator or array is symbiolic of total
gain
(poyntings vector) and where with respoect to a sphere the energy
contained within the sphere is equal to the energty outside of the
sphere.
In the Faraday cage the outside surface is covered in charges carried
by particles as is the inside surface so the areas can be considered
equal and 100% efficient energy transfer. The total energy is
realisable ONLY when transfered as a time varying current from the
inside of the sphere.This being the addition of the charges carried by
the particles on the inside and the outside of the conductive surface.
Thus this is the experimental results o0f Faraday that leads from
Gauss to Maxwell.
With respect to radiators the analogy between the surface area of a
sphere equates with the circle that encloses a radiator, say a yagi.
This is provided by Jasik as a approximation of gain by visualisation.
This same analogy was applied by Steven Guest on his antenna paper
presented to the IEEE for an electrically small radiator' where he
showed that by "crushing" a radiator into a state of equilibrium for
insertion into a half hemisphere as per Gauss.
Thus with all this interlocking of facts when comparing a Faraday
shield with a radiator opponents of the particle aproach are now in a
position of showing an electrical field cancelling a magnetic field
both of which are a measure of energy alone and not mass to produce
a addition of fields so that somehow a time varying current is
obtained
which a receiver can use.
Compare this with the proposition that a photon is a relatively
unknown,assumed to be without mass in terms of mathematics that
apparently is a breakaway of energy from mass in a similar form to a
fireball. Frankly the idea of the eyeball being a small Faraday cage

to manufacture a signal to the brain is a much better supposition by
those who rule physics of the day.
Art

Happy New Year to you too Art,

Interesting ideas, as ever. I don't see anything to disagree with in the above as you have stated it. As you say, the exact nature of the photon is relatively unknown and by virtue of the fact that there is a formula that allows energy to be converted to mass and vice versa, there is the possibility that photons will one day be discovered to have an infinitesimally small mass.

I suspect the missing ingredient in my water analogy is the bond that binds the atoms together. The ancient concept of an all pervading ether throughout space may substitute in electromagnetic waves providing a substrate to bind the electric and magnetic fields and perhaps also be the reason for the limit of the speed of propogation of radio and light waves. In universal terms 186,000 miles per second is not very fast. Perhaps there is a slight pause in propagation as the photons transition between electrical and magnetic fields, at the moment of transition? It seems there may be an 'ether' after all.

Reports of experiments that appear to demonstrate faster than light propogation is possible in the laboratory indicate that we are still missing something vital in our understanding of electromagnetic waves in all their forms.

You are not alone in your frustration at modern physics using pure maths to arrive at an explanation for the way things work. Many mathematicians in the Victorian era were unhappy with quaternions and the use of imaginary numbers to arrive at the solution to previously insoluble problems. The use of imaginary numbers (like the square root of minus 1) to balance equations divorced mathematics from the everyday world in which things could be directly physically verified at each step by measurement. Of course this math is used everyday in radio to calculate standing wave ratios and for antenna matching. It works in as much as you calculate the values according to the formulae and get an answer that matches (generally) what is found when you build the antenna and feedline. I have never quite got over the disquiet that an imaginary number is vital to solve the formulae myself, even though I have been taught how and why it is required.

Perhaps it is time for a newer new mathematics to address these problems and not resort to string theory which seemingly gives the answer to everything and nothing unless you already know what the answer is. Just like Douglas Adams book Hitchhikers Guide to the Galaxy when the computer answers that the solution to life, the universe and everything is 42.

Have a great 2010

Mike G0ULI

One final note
When mass changes state there is a loss or gain in energy at a near static temperature! If energy has mass then it should be measurable at both ends of a liquid state change stages. I have heard nothing that relates to that which knocks my thoughts of energy measurement in terms of temperature, into a mess. Looking at it from mechanical "work done" angle is way beyond my pay grade.
I have just made a 6foot sphere of aluminum mesh which I will try to attach a Bernoli type nozzle so I can try to measure the half power width as well as the Take off angle as I raise the ground mounted apparatus from horizontal to some where above the grazing angle. Forcast for weather in the next two weeks is negative temperatures (F) so all activities have come to a close. Now I can muse about the nozzle being in the confines of the sphere versus outside of the sphere. Certainly inside means an increase in Eddy currents which constituts losses. On the other hand outside suggests a loss because it requires a larger sphere..... Maybe a comparison against just an opening is called for

One final note
When mass changes state there is a loss or gain in energy at a near
static temperature! If energy has mass then it should be measurable
at both ends of a liquid state change stages. I have heard nothing
that relates to that which knocks my thoughts of energy measurement in
terms of temperature, into a mess. Looking at it from mechanical "work
done" angle is way beyond my pay grade.
I have just made a 6foot sphere of aluminum mesh which I will try to
attach a Bernoli type nozzle so I can try to measure the half power
width as well as the Take off angle as I raise the ground mounted
apparatus from horizontal to some where above the grazing angle.
Forcast for weather in the next two weeks is negative temperatures
(F) so all activities have come to a close. Now I can muse about the
nozzle being in the confines of the sphere versus outside of the
sphere. Certainly inside means an increase in Eddy currents which
constituts losses. On the other hand outside suggests a loss because
it requires a larger sphere..... Maybe a comparison against just an
opening is called for
Cheers
Art
Cheers
Art

Hi Art,

Minus 2 Centigrade here with snow on the ground and more forecast, so not
the weather to be outside although tropical compared to your QTH. The energy
released and absorbed when mass changes state can be quite considerable but

may be unnoticed depending on the mass involved, its thermal conductivity and the environmental background temperature. The famous e = mc2 equation demonstrates that huge amounts of energy are required to equal a very small mass and that assumes 100% efficiency in the conversion. Much lower conversion efficiencies are observed in the real world so the effects are barely measurable. Burning materials in a sealed but transparent container should result in the container being lighter than an identical one containing unburnt material due to the emission of heat and light, the conversion of mass to energy. A famous Victorian experiment showed both containers to weigh exactly the same. Of course they weren't trying to demonstrate mass to energy conversion at the time, rather that the materials were being converted from one form into another and that in a sealed system nothing was lost or gained. In that respect the experiment was a success. The exquisite accuracy needed to measure such effects such as loss of mass due to conversion of matter into energy is beyond all but the best equipped modern labs.

Cheers

Mike

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

I don't remember if the question was ever settled. There were a couple of philosophers with Pythonesque silly names who asked Deep Thought the Meaning of Life, the Universe and Everything, and whose equally silly named decendents spent their final years cleaning up on the chat show circuit, but the computer designed to calculate the original question got thoroughly panned by a small fleet of yellow butter-pat shaped ships full of petulant Vogons and Dentrassi chefs.

But I sort of sense how Douglas Adams thinks, a small and persistent obervation blooming strangely. No-one ever spelled out that 42 came from seven sixes or six sevens, but 'all at sixes and sevens' is an English colloquailism that Douglas Adams would not have ignored. Basically the idea is chaos, but not exactly chaos, just an arbitrary collection is decreet entities that exist in no clear relation to each other, so all kinds of silly possibilities exist. Fits, no? :) And don't get me started on how I think he came up with 'The Long Dark Teatime Of The Soul'...

As the original poster (I presume it was Art) is in the habit of
quoting a German surveyor of the early 19th century; it should have
been settled by the Reichoffice of land boundaries.

These threads seem to be started in the vein of a breathless discovery
of an announcement tucked away in a locked file cabinet in the
janitor's closet in the third basement revealing plans for the "new"
hyper-Hohenzollern horse carriage expressway bypass - as much as the
original comment, responses and counter-responses are so distinctive
by fulfilling that metaphor.

That reminds me of another great bit of writing, on military standards, I found it online somewhere, it explained how the Roman roads were decided based on uquestrian travel, went on to show how the same standard measures persisted through centuries of rail travel and ended up explaining why it is that the scale of the solid rocket booster of the most advanced form of orbital transport known was exactly correlated with the width of a horse's ass. :)

Basically true. The ruts on Roman or older roads caused by wagons and carts meant that any cart not conforming to a standard wheel width would tip over or lose a wheel. Rail wagons were adapted from road carts and so the standard was maintained through the Victorian era. Modern machinery is still essentially set up to those standards to maintain compatibility with earlier equipment and so that older machinery can still be maintained. Bit like the DOS prompt still being available in Windows?

Actually it comes out during the TV play and at
least one of the books that it's "what is 9 times 6?"

Adams denied what many here should quickly figure out.

That prompt SHOULD be there. :) The real problems with M$ come when they try
to break with history, not when they honour it. Given that their initial
```

survival depended on direct inheritance that should be evident. OS's that have real security like OpenBSD don't reject their roots, they GROW on them properly. :)

Which reveals an interesting point... The size of standards can easily be arbitrary. So it makes good sense to go with something that has historical context. That way we can efficiently revert to whatever earlier form we need at will. The only way to improve this proces is to think ahead better at the outset. Not easy, given that ancient Rome was in no posotion to imagine a space flight program's requirements. Actually, of those it COULD have imagines, it provided the groundwork for extremely well despite not having any way to imagine them. Likewise, people underestimate older and simopler computer systems at their peril.

Ha! I bet that only runs in 32 bit protected mode, too. >:)
(Which I could easily be wrong about but it's the kind of silliness that
might be true, as often happens when people think that plants continue to
grow when you cut their roots off, as M$ appear to do. For the record, I
stay with W98 for this reason, it was the latest M$ OS that grew firmly on
the roots that Windows was designed for (and a lot of stuff I need depends
on it anyway)).

I'll buy that it's a lot older, that's the thing about roots, they trace out further than any effort to cut them does. And given how much they cover, it seems unwise to consider them a limiting factor. Sure, if you want to fly, can't stay rooted, but even that little homily doesn't mean that Arthur Clarke wasn't right about the space elevator. :) We won't go far until we build one. And what's the betting its tramlines will still be the width of a horse's ass or two?

I never saw that one.. Read the books, but I don't remember that, at least not with much meaning. Maybe just to indicate human capacity for coming up with wrong answers from wrong questions? I doubt he ever spelled out what the real roots were. A good magician doesn't deliberately and publicly spoil the illusion (or in his case, allusion, perhaps). The one thing I'm fairly sure of is thet the references were cultural, colloquial, and that's why so many people got it. Without that it might have just been another impenetratable space opera with humour thrown in.

Well, I wondered about non-euclidean geometry for a moment, then remembered
Greg House saying something about working smart, not hard, and no-one said I
couldn't plunder Wikipedia, so....

Actually, before I got there, I wasn't even sure if what Adams had denied was
that "six times nine equals thirteen is wrong", or that he denied the more
interesting case that it was its correctness in base 13 that explained the
'answer'. Apparently he did deny it. Which doesn't mean it isn't true. :) But
according to Wikipedia's stuff, he chose a small number that looked ordinary
and totally unprofound. Which means that he let whim, i.e. unconscious
conditioning hold sway, without attempt to mediate it. Given that the English
colloquilasm would never be entirely far from a writer wose native language
and culture was English, I stand by my 'theory'. :) Though I'd like to know
if he was ever directly questioned about the 'sixes and sevens' thing and
denied it. Even then, he would be telling the truth if it hadn't been
conscious. MUCH more like he was influence ny this that by base 13, no?

Maybe you should get me started on my idea for The Long Dark Teatime Of The Soul, you might like it. :) The only thing I'll say about it now, unprompted, is that in this case the allusion isn't English, it's French.

I also found this:
"Stephen Fry, a friend of Adams, claims that Adams told him "exactly why 42", and that the reason is[12] "fascinating, extraordinary and, when you think hard about it, completely obvious." However, Fry says that he has vowed not to tell anyone the secret, and that it must go with him to the grave."
http://en.wikipedia.org/wiki/Phrases_from_The_Hitchhiker's_Guide_to_the_Galaxy

I have never met Stephen Fry, and I suspect he wouldn't confirm my idea if I did ask him, but it would fit, given the way thoughts run if you ponder it for a while. Considering the phrase "all at sixes and sevens" in the context of the way HHGTTG works is revealing to the point that even if it really were the original basis, I wouldn't consider it a spoiler if I'd been told either before or after thinking of it for myself.

Can't help wondering when people are going to talk about antennas again. :)

23. Matching impedance on 900 MHz Yagi stacking harness

Newsgroup: rec.radio.amateur.antenna
Date: 2010-01-02 17:08:16 UTC
From: mr1956 <mr1956@comcast.net>
Message-ID: <39f0628c-9bc2-4978-bd79-c1ff4468cd57@m11g2000vbo.googlegroups.com>
Source record: 11423

I have posted on here before and found the member's comments very helpful so here it goes again.

I am trying to stack two Yagi antennas to form a ground station to receive GPS data from an experimental rocket. The rocket portion of the system has already been tested but now I have two antennas to couple together to make up the receiving end. The particulars are as follows:

I have two 11 db 900 MHz Yagis (Pacific Wireless), both of which have 50 ohm pigtails. I am trying to hook these together in a cross polarized fashion and need to insert two 75 ohm impedance matching cables so that I end up with 50 ohms at the cable end attached to the input of my receiver. Basically, there will be the two antennas, matching sections, a tee connector, then the single coax going to the receiver.

I figure that 75 ohm RG-11 coax should work for this purpose and am trying to calculate the correct length of these impedance matching sections. One formula I have found online is as follows:

Length (feet) = 246 * VF / Frequency (MHz)

The transmitter sends RF via Frequency Hopping Spread Spectrum from 910 to 918 MHz; consequently, I am using 914 MHz as a baseline.

When I plug in the numbers, I get a length of about 2.1" for the length of the 75 ohm matching sections. Needless to say, it will be difficult if not impossible to do a 2.1" length of RG-11 cable with two connectors. I have considered basically fabricating a "tee" section out of two short lengths of the 75 ohm coax and RG-8 going to the receiver (soldering the whole thing together), then connecting the two Yagi antennas to that.

I suppose my question is this: Is there a longer multiple of wavelength I can use for the impedance matching 75 ohm sections to develop a more practical design for what I need? Or, am I stuck with the 2.1" length due to the frequency?

Thanks,

Curt Newport

Hi Curt,

To answer your last question first: you can use odd multiples (1, 3,
5, 7...) if your initial computation was correct. Consider, if your
computation contains errors, they, too, will multiply.

Computations aside, a receiver rarely needs exact matching when "close
is good enough." Two 50 Ohm antennas in parallel or series are not
seriously off. The mismatch loss would probably amount to less than 1
dB whereas your using two crossed antennas is in an effort to recover
from the loss of polarization mismatch that can exceed 20 to 30 dB.

As a practical matter, have you tried testing these antenna issues at
ground level? There are certainly complications that ground proximity
can introduce (reflection from ground being principle among them). As
a first pass approximation, however, you can come to some feeling for
many issues without having to loft anything into the air. Insofar as
polarization mismatch goes, ground's proximity would tend to dilute my
suggestion as ground and anything that is in proximity would tend to
offer many reflections some of which don't come anywhere near your
final application.

Richard:

Yes I have tried testing one of the antennas at ground level but that
is not really representative of the reality. I suppose the bottom line
for me, is that how much of a loss and I looking at if I simply hook
these two 50 ohm antennas in parallel to a tee section, then on to the
receiver? The whole reason to have the two yagis to begin with is to
increase overall gain and insure that the polarization between the
transmitting and receiving antennas is good enough to maintain a link.

If I elect to do a multiple of 1/4 wave, then how does that work out with the formula regarding frequency?

Thanks,

Curt Newport

Yeah, but simplicity and sometimes clarity usually fail to get
funding. Seen any government money go to the myriad of simple fusion
schemes?
<http://www.fusor.net>
Nope, even though some of them may actually eventually work. It all
goes to gigantic fizzix experiments which are anything but simple and
to my limited intelligence, not very clear.

>If the public had a better understanding of engineering and science, things
>like Betamax, apparently better tech than VHS according to most who discuss
>this issue, would have won, to the advantage of most people, not just the few
>who forced the 'war'.

Beta is often used as the poster child of technology versus cost. Sony
wanted license fees for Beta, while VHS was essentially free. The
public voted with their dollars and VHS won.

Moral: The GUM (Great Unwashed Masses) are cheap.

Incidentally, the same thing sorta happened with the battle between
the RCA all electronic and CBS color wheel schemes for color
television. The FCC almost went with the color wheel scheme because
RCA hadn't really shaken all the bugs out of their system.

Fast forward a half century and we have the same FCC voting on digital
television standards. If technical superiority were the criteria,
COFDM should have won over 8VSB. However, such decisions are not made
on the basis of technical superiority. The public could have been
better educated on the issues, but the decision was made by a
committee of politicians, not the public.

AM stereo and HD radio, versus satellite radio (XM and Sirius) is an
oddity. HD Radio, AM stereo, and DRM should have been the winner,
because they are the cheapest and simplest. Yet, satellite radio is
far more popular. The real difference is that satellite radio started
out with no commericals, and slooooowly infested the programming with
them. People were willing to pay for what they preceived as
commercial free programming. I guess the GUM isn't very well educated
on the the technology, but it's certainly not stupid.

>Conflict is bad enough, but the one thing that can most
>effectively redeem it is if it is won by whatever was most right, or useful,
>or helpful. And if enough people grasp that well beforehand, the conflict
>probably wouldn't happen so much.

I presume you've never attended (online or in person) a standards committee discussion. It's fortunate that the technical debates are mostly done electronically or at a distance, as I'm fairly sure some of the proponents of extrememe technologies would settle their differences in the parking lot.

>Maybe I should shut up now, but this has got to be THE slowest day of the
>year. And I include most of the last one in this assessment.

Not for me. For some odd reason, I'm getting a series of customer calls asking for help with various Christmas toys and gadgets. They apparently have stared at them for a week, given up, and now call me for help. For example: "I got this iPod thing. How do I make it play tunes?" I just finished an over the phone Netflix appliance (Roku) setup. My guess is public understanding of engineering and science has a very long way to go.

Hello Dr,

Well, I've been on the East Coast for several weeks and am just
catching up with your particular problem (which is not too uncommon
for SWL'ers who post here).

Many suggestions have been useful, but some contra-indicate others,
while some merely rely on lore and superstition.

One of the last suggestions, from JIMMIE, is probably the single
greatest boon for signal strength: Ground. Ground is always the least
appreciated component, and is always the single most important one.
Ground for RF is not always the same as the ground for safety. Worse
yet is that mixing them can sometimes introduce grief (AKA ground
loops). ALL grounds should eventually find their way to the service
ground. This advice serves both safety and engineering. More can be
said - but we move on.

One antenna does not always work for all bands (not without a lot of
work and the ability to change its polarization). As such, two or
more antennas are necessary for SWL'ing. They don't need to be
isolated to one band, but if any antenna is resonant for one, it will
probably be difficult on another band that is twice or half that
frequency. Thus you add another antenna that is half or twice the
first's dimension. The benefit here is that they can be wired to the
same feed point with little interaction between them. More can be
said here too.

Matching with a one-size-fits-all doohickey is pabulum for the masses.
When it is tossed into the mix, it usually forces the user to add the
components already described above that are responsible for most of
the benefit attributed to the doohickey. Hosanna's are misplaced.
More can be said here, to not good outcome.

Matching with an antenna tuner (yes, I am aware of the irony in its
name) satisfies all issues (except for the transmission line loss - if
it matters) of matching. The tuner's responsibility is to see to it
that an unknown source is matched to an unknown load (that is why it
has so many adjustments). You can use any Ham grade tuner, get one

without a meter to save the big bucks. Whatever product that is designed for the ham bands is satisfactory for the SWL bands. Of course, you could build your own (what a concept!).

Matching with a preselector takes the antenna tuner one step further, and protects your receiver from the scourge of these "modern" designs: intermod. The SWL-monkeys who demand the ability to "quickly" tune up different bands/frequencies usually whine and squeel about the difficulty of tuners and preselectors (and in the same breath praise the doohickey's font of blessings). I let them indulge in their illusions and say no more.

INTERMOD is the silent killer (as they used to say about high blood pressure). A strong station (a nearby AM transmitter in town) can easily close down your 31M listening experience by simply driving the AGC into overload without you being aware of it. Preselectors and Tuners will drive down that off-band signal, peak the selected frequency, and give you what you tuned for in that band. Beware of imitations that suggest they do the same without tuning (what a crock).

As for that antenna impedance. Others have suggested a myriad of possibilities. The first active component's shunt reactance (often the base-emitter capacitance) is the limiting factor even when humongous resistance bridges those same points. Resistance is for bias folks. More can be said, but enough has been said here.

Feel free to ask for more to be said.

Thanks. :) Well, my plan is to use a ground at the antenna end, right underneath it. My neighbourhood problems recently were solved when a guy on the first floor pissed off someone enough that said someone blew their flat door in with a shotgun! So the whole problem ended with a neat flameout a few days ago. I couldn't go out there rigging antennae while paranoid criminals were still active, it's seriously asking for BAD trouble. Right now I have the lesser problems of dental and other bills imminent, but I'll get a good 4' ground rod and rig up an 18' vertical whip as I learned of in details I posted about earlier. I understand that good reception depends on a good compromise between selectivity and sensitivity, and no doubt the antenna 'tuner' helps with that, though I'll mainly be concerned with good ground and

local common mode noise rejection. My first attempt at the line between antenna and receiver will be a balanced line with a toroid at each end for current isolation and possibly the suggested Norton preamp on the receiver input, but I'll try without it first as I suspect I'll get enough signal strength to satisfy me for a while. If I have to use coax I will but I'll try the easier options first. This basic plan does involve a 10:1 ratio in windings on the far end toroid which should help smooth out peaks of resonance as described by John Doty and others as mentioned before, and if nothing else, drives a stronger current in the balanced line part of the system. I'm no longer much concerned about matching impedances, but I will be watching for results of changing antenna length if resonance seems to be an issue. My interest in the 'doohickey' or any other widget was mainly in what appeared to be a means of reducing the difference in signal strength extremes due to resonance. I understand that if I subsequently have to select the weaker of two close stations I'll either have to add some 'trap' for a specific offender, such as a trimmed lengh of unterminated coax (though as far as I know, that trick is usually reserved for much higher frequencies), or use a manually tuned system which I'll explore if it becomes a dominant concern.

Gubmint won't touch it till private efforts start working. Was the same with canals and railways. :) And mining. And hospitals. And, perhaps, large scale space explorations. Very cool site, I'll try to follow some of that stuff. I suspect small scale fusion will be the answer to many problems, far more than it's likely to cause.

Gubmint by GUMint? :) I amuse myself.... I guess FireWire might suffer the same way, it wants royalties in the price of every plug. I think that one will be a survivor though, it is very good. But it won't be as common as USB which doesn't.

That never helps, but people are getting very wary of politicians, which might help, if they realise they have to think that bit more for themselves. I can accept that pure technical superority isn't always a vital justification, too. For example, cost, to me, is a vital engineering parameter. As in not over-riding, but never to be ignored. Substitute 'cost' with 'ease', 'readiness', and it quickly gets convoluted. Even 'self-interest' creeps in obviously, but I guess it depends on whether it's enlightened or not that matters most. The other main problem is short-sightedness. Most really successful tech-driven economies are LONG sighted, they don't make expensive errors they can't fix later. That said, even the best of those can rest on their laurels and lose ground, as Japan seems to have done.

Interesting. I sometimes use a similar argument in my defence of Usenet when debating with people who think it's dying. Given how fast it loads, I think we can expect many 'web2' refugees, as it happens.

Nope. :) But I have seen infighting over ideas in forums. I've seen experts stamp on good ideas then try to assert their own ideas which were weaker, and because they had a strong academic background, most bystanders were quick to curry favour with them. I figured the best answer was to go alone when I have

a good idea. First, they muscle in only when someone's already staked a pitch, so the easiest way to undermine that is to break camp and move out. Second, asking them for assistance will either result in conflict, or stolen credit. Even systems like patenting invented to solve such issues fails because legalistic presentations seem more to do with emotive attempts at squatters' rights than any real defence that might as easily be done with copyright law. None of which stops acrimonious court squabbles. So things like those small scale fusion experiments will only reach success by being done, repeated, by those who will do it without waiting for support. I think the main reason 'big' science gets the funding is actually simple: it's too big to actually be done at all without it.

Yep. Though given the speed, I have to sympathise with both 'sides'. I loved to take stuff apart and put it together (especially when the latter saved me from punishment if the former would otherwise have gotten noticed), but when confronted with bloated complex operating systems that have been cleaved from the roots that led to their existence, I balk too, the same way many do when told that only maths, and not human observations, will tell them anything new about reality. And I'd rather stay with something whose engineering I can grasp well enough to stand some chance of maintenance.

Actually I strongly suspect that this distance between science and tech development and public comprehension won't be reduced until the tools enabled by quantum mechanics start showing us things that shift the current paradigm so much as a result of their new obervations, that people have something really big and new to think about instead of being compelled to beleive that all is run by chance. I think quantum theory largely got us into this mess, but I also think it will get us out. But I have no clue how, other than what I just said.

A 42 metre long, inverted V, fed through an ATU makes for an effective and
cheap all band antenna, although perhaps not the ultimate antenna. :-)
Perhaps an antenna array mounted 42 metres above ground? That would be some
tower system to have in the backyard.

Mike G0ULI

Hi Curt,

To your last question: frequency and wavelength are inversely related.
Compute at any frequency, convert to wavelength and use any odd
multiple of 1/4th wavelength. This, I presume, you are already are
familiar with. What I further presume is the basis of your question
is more oriented to the span of frequency involved
>>910 to 918 MHz; consequently, I am using 914 MHz as a baseline.
which is good as it is going to get.

As for using a T, as I posted earlier, the loss there (more for
transmitting than reception) would be less than 1dB. The additional
complexity of more lines, more connections, more components could
easily equal this OR you could find optimal results = more loss than
0dB, but less loss than something less than 1dB.

The difference between more than 0dB and less than 1dB is pretty slim.
If you feel you need to go there, you should be looking at working on
a path loss and power budget. I don't think you've offered that here
in the past. Two yagis set in cross polarity (at right angles) does
not increase "overall gain" except in the sense of insuring that all
polarizations are covered. In fact, given the random orientation, you
stand to lose "overall gain" on average when comparing one fixed yagi
to a known polarized source. In fact more than 1dB (probably 3).

Again if 1 to 3 dB is important, other solutions need to be considered
and you really need a more elaborate analysis.

This does not acknowledge the significance of INTERMOD problems. Experience may have to teach that (when you make all these improvements and have poor results for your effort).

>My first attempt at the line between
>antenna and receiver will be a balanced line with a toroid at each end for
>current isolation

This is a very, very curious novelty. You do not describe a "balanced" system with a ground rod and vertical, so any effort at "balanced" lines is window dressing only. The reason for placing "balanced" within quotes is due to the inordinate care and skill required in obtaining a balanced design. It is more often achieved with coax. Too often, "balanced line" is approached with the mysticism of universal relief for whatever ails a listener.

>and possibly the suggested Norton preamp on the receiver

This is the doohickey I spoke of. It is basically the refuge
accessory of the lowfers where the span of frequencies is, maybe,
three to one and not like the ten to one of HF SWLing.

>I'm no longer much concerned about matching impedances, but I will be
>watching for results of changing antenna length if resonance seems to be an

This is at cross purposes. You don't have many realistic options of
changing antenna length (height) as you do with a simple tuner when it
comes to matching.

>My interest in the 'doohickey' or any other widget was mainly in what
>appeared to be a means of reducing the difference in signal strength extremes

>concern.

Traps don't work very well for adjacent AM/SSB stations, you need
cascade XTAL ladders to do that. Tuners, also, can only operate
within the combination of number of reactive elements and Q.

Please respond to your perception of the problem of INTERMOD as it is,
as I said, the silent killer of reception.

Sir
If you have the time to try, make a sphere about 4 Ft diameter of aluminum window mesh. This gives you total coverage of all polarities and you don't need a rotor as you have full sky coverage. 6 panes 2 foot wide stapled or riveted together will do the job. This is a Faraday cage where you ground the outside and connect the inside to your radio. Cost of alum window mesh is minimal and it does not take a lot of time to make.Nothing ventured nothing gained! Hula hoops inside will help to keep its shape.
I assume that the idea of total sky coverage with total polarity coverage will provide you with worthwhile advantages over the route you are contemplating making it worthwile to spend a day making one.

Richard:

Your reply is noted and let me do some figuring and see what I come up
with.

I agree, that the cross-polarization of the two yagis is more critical
than the overall gain as this is the greatest unknown. In other words,
I have no idea as to the orientation of the transmitting antenna
relative to the receiving antenna, except during the boost and descent
phases. Those are fairly predictable because the rocket goes generally
straight up, arcs at apogee, then descends with the bottom end down on
the large drogue chute.

I have found a power divider made by Cushcraft but am wondering
whether or not it is worth the investment.

Regards,

Curt Newport

I haven't a clue about intermod, yet. One thing at a time. Right now I see at least three contradictions (re ground rods, transformers, and feedlines) with advice from several people, one of which (the guy who wrote the description of the antenna and balanced line I mentioned) is part of a group of hams who is turned to for advice by the others. No guarantee of correctness, perhaps, but if I keep on being told I'm wrong when my stuff is coming as directly as I can get it from others with experience, then as far as I'm concerned I'll

do what I think best and get out of the crossfire. Specifically, many times I've seen advice that service grounds are not adequate because of common mode noise and local currents, hence the ground rod you vehemently negate. I can ground to service ground at near end but if the receiver is on batteries, not connected to anything except a transformer coupling RF from the antenna, then the ground only needs to be at the antenna end, according to advice I've seen in several places. Even if I do ground to a water pipe or other local ground, all advice I see until now insists on having a ground rod as close to the antenna as possible, no matter what else I do, yet now you urge against this. I will stop asking for advice if all I see is vigorous contradiction between people who claim knowledge I do not have. Diverting that disagreement to one with me doesn't alter this, I did not originate the info behind the choices I am considering. Even if all the various contributors come here and duke it out between them it appears I'll be none the wiser.

To save time:
"http://www.kongsfjord.no/dl/Antennas/The%20Best%20Small%20Antennas%20For%20M
W,%20LW,%20And%20SW%20rev%202.pdf

The start page for that link is here;
http://www.kongsfjord.no/dl/dl.htm"

(Copied from a post by 'amdx' earlier in this thread). The line IS balanced,
as it carries only its own internal current, driven by an isolated coupling
with the antenna circuit. Anyway, if he's wrong, there's not much point in
taking it up with me, for obvious reasons. He wrote that. I didn't.

The term Intermod is probably mis-direction if you research it.
Basically, if an nearby AM/FM/TV transmitter (and nearby can be on the
scale of several miles) happens to excite your antenna; then its
developed voltage will overload the frontend (Intermod follows, but
the products are not what I am emphasizing here). This overload can
be many, many kHz, or MHz from the intended and tuned signal; and yet
this frequency remote signal will develop an AGC that drives down gain
on your intended signal.

This characteristic is VERY common for untuned frontends in modern
receivers. It is not often noted for poor antennas (those whips, when
they are used for SW), but when a real antenna is attached *BINGO*
sensitivity goes down the toilet. By providing a tuned input, the
side-signal that would otherwise silently drive AGC is attenuated, and
AGC is developed only by the in-band signals.

>Right now I see at

A reasonable posture.

>Specifically, many times
>I've seen advice that service grounds are not adequate because of common mode
>noise and local currents, hence the ground rod you vehemently negate.

I don't negate its use, I say that it is NOT RF ground. If you tie
this ground rod to the service ground, then that wire will probably
act more in your behalf than either "ground." There is a world of
difference between safety grounds (what those rod-thingies are) and RF
grounds (which often don't go into ground at all).

Ground is a long and rich story that has been celebrated in this group
for years. It deserves respect and attention well beyond these few
words.

>I can
>ground to service ground at near end but if the receiver is on batteries, not
>connected to anything except a transformer coupling RF from the antenna, then
>the ground only needs to be at the antenna end, according to advice I've seen
>in several places.

To your specific arrangement - quite true. However, many who have claimed to have made every precaution then connect their receiver to an amplifier, computer, what-you-might-call-it and a new path to ground winds its way through interesting environments that are RF rich.

>Even if I do ground to a water pipe or other local ground,
>all advice I see until now insists on having a ground rod as close to the
>antenna as possible, no matter what else I do, yet now you urge against this.

I urge against mixing grounds. Such things arrive by the most benign and seemingly inconsequential actions.

>I will stop asking for advice if all I see is vigorous contradiction between
>people who claim knowledge I do not have. Diverting that disagreement to one
>with me doesn't alter this, I did not originate the info behind the choices I
>am considering. Even if all the various contributors come here and duke it

Attention to one detail at a time helps, but a lot of this arrived through responding to the query for antenna port Z. Those adjuncts that massage input/output Z also fold in the discussion of ground.

Convention has it that you start a new thread for each side-topic that drives you into conniptions. Asking about the facts and foibles of ground would be a good start on a new thread - especially when Art's wet-dreams descend into discussion of particle duality self annihilation driving all participation away from antenna design. For instance "Why are ground rods considered insufficient for RF application?"

I am content to respond to either discussion.

An example of invention driving the discussion rather than the need
being satisfied.

Simply put, there is absolutely no reason to use a "balanced" line. It
is window dressing for the circuit which IS balanced (and balanced for
no apparent reason for this unbalanced source). Metaphorically, it is
like adding a clutch to an automatic shift. Yes, you can do it. It
might appear to be elegant. It will certainly work. But why?

Try asking why the trappings of this novel design don't bring some
solution in a new thread. You might stumble at offering the problem
it pretends to solve. (I will anticipate it has something to do with
noise, THIS will certainly raise a lot of catcalls.)

> you linked to...

The Sangean ATS-909 along with similar radios are designed to resolve signals from the whip antenna or in built ferrite antenna. Attaching 8 to 10 feet of wire to the whip will bring in more stations but depending on location may well pick up so much extra signal as to cause intermodulation and AGC limiting preventing reception of the weak signals you want to receive.

As stated earlier, the front end of these receivers is wide open and the front end is exposed to the complete spectrum of transmissions received by the antenna.

There is nothing inherently wrong with the receiving system you have decided upon but it will undoubtably overload your receiver with signals and you will be puzzled as to why the reception seems poorer with more noise pickup rather than less.

As Richard has stated you need some form of preselection to filter out the unwanted signals before they get into your radio. Basically this is a tuneable filter which only allows through a single band of frequencies at a time. The following site explains the essentials.

http://www.dxing.com/tnotes/tnote07.pdf

You can buy commercial preselectors but they will probably cost as much as your radio. As they are generally passive devices built from a set of switched coils and a variable capacitor they last forever and old ones do come up from time to time at junk sales and the like. It is possible to make a simple filter to cover just one or two bands that interest you.

By all means, try the external antenna system but be prepared to buy a 'better' receiver with front end band pass filters or a preselector.

You can have too much of a good thing when it comes to receiving antennas. A bigger receiving antenna won't bring in signals from further away. If they are there, the receiver is probably sufficiently sensitive to pick them up already. What the bigger antenna will do is raise the level of all the signals it is picking up and feeding into the receiver and that includes

noise, and other unwanted stations. That is why you need additional filtering to cut down the unwanted signals and allow your receiver a fair chance of demodulating what you actually want to hear.

Argh! OK, another "hint".

Has anyone ever heard of anything besides base 10 arithmetic?

Ok, this is cool, I understand that, and I also see that it doesn't really
concern intermodulation products as the initial problem is a bigger one if it
occurs. Can't help wondering why a receiver doesn't do some tuning before the
AGC for exactly this reason, but never mind...

True, I don't doubt that for an instant, but it's also a question of what is practical, and what is recomended by most people I've read words from at times during the last 30 years or more. While I know that CB'ers would just stick a magmount on their car's steel rooftop as often as not, and have read of other schemes that place some small horizontal plate below the antenna, there's a lot of scope between that and a rod driven into salty ocean shoreline. Most people I ever came across asserted the importance of a ground rod local to the antenna to couple with the local water table which is as close as most ever get to the ocean unless they really like getting their feet wet while they sit around at home. The proximity is as close to the point where they want to pick up RF as they're going to get, and means less noise from buildings full of electrical stuff picked up on metal between antenna and whatever other ground might be provided elsewhere. This has been the ONE common factor in pretty much everything I've seen on land-based AM reception. Anything that directly appears to negate that advice makes it hard to know what to trust, and certainly needs to be clearly explained.

>

I agree. The moment I try to connect to a system that includes a computer, mixer, multiple supply grounds, as mine does, I'll be using a local service ground and improving it the same as I would for audio, though it's currently ok for that, at least. It already uses a star grounding system where possible, as recommended by audio studio designers and others. There's actually a supply ground rod outside the front door too, which presumably helps more than the original wiring 15 years ago which didn't have that. (But note below, where I mention isolation).

>

Hence the star network I mentioned, advised for audio setups.. It's kind of why I wonder about what many suggest, grounding a coax at both ends, and even in the middle if you want, and certainly to bury it. More importantly it's why the Dallas Lankford design appeals to me. Isolation baluns that transfer energy rather than use direct contact coupling look like a good way to avoid the ground problems while also avoiding local noise pickup because the twin cable will have good common mode rejection as it passes into the electrically noisy bulding. (Though I can't help wondering if Dallas Lankford also tried balanced microphone cable with a screen grounded at one end, just to see what happened) Such methods have long been used in audio; is RF below 30 MHz really so different in this case? So long as that line doesn't have dire resonances of it's own, isn't attenuation the only big risk? Dallas Lankford certainly thinks it works after working with it for at least 2 years. He says that if you do it as described it will be low noise. (As opposed to 'reducing'). I don't think he's claiming any means of reduction, just saying it's lower relative to inherently noisier systems, if wired as decribed. Based on what I know, the claim seems good.

Agreed. But this is why instead of asking more questions whose answers I am probably not prepared for, I described the simplest and apparently best scheme I'd learned of so people see it whole and work from there...

> Convention has it that you start a new thread for each side-topic that
> drives you into conniptions.

Ah. :) Well, I thought that's exactly what would annoy people most. If something directly arises from discussion in a thread, most people tend to keep it there. I already do start a new one if I'm certain the issue is different, and if I'm originating it.

> Asking about the facts and foibles of

> Richard Clark, KB7QHC
>

Well, sure, if I am asking a direct technical or practical question. But while I'm still slightly reeling from what appears to be a dissention with what otherwise appears to be good advice, I like to keep the discussion in one place, otherwise confusion reigns and spreads to many threads. Trust me, that might annoy people. :) At least in this thread it might be useful to anyone who has that radio.

One reason I chose it is that it isn't trying that hard for extreme signal capture. It appeared to be small, easy to use where I have limited space, and include a transformer that I have read in numerous places partially solves one of the main reasons for strongly differing signal strength with frequency.

The pre-selection thing isn't a problem, I can see why that helps, and did so much earlier than now. The point that disconcerts me strongly is what appears to be significant difference of opinion between experts, especially when it applies to things as well established as ground rods. Again, this is why I won;t just ask questions. Context is clearly everything, so instead I describe the whole scheme I'm considering. Ultimately it's quicker that way.

Yep, that's a nice one. I still like mine better though. Adams liked to play
with language directly, it would have appealed to him even if it wasn't how
he got there.

Any thoughts on tea? That was another mild obsession with him, and extends
obviously, though strangely, into the Teatime thing. Consider it a hint. :)

The answer to your question is yes. You can use odd multiples of the calcuated length (my calculation give 2.13" for PE-insulated cables like RG-11, or 2.25" for teflon insulated cables. For foam-insulated cables, calculation must take into account the actual cable velocity factor).

However, at 900 MHz, building the coax combiner you have described would be an headache, due to the difficulty of precisely calibrating the coax pieces length and to verify their performance.

For a receive-only system a solution you may consider is to use a small preamplifiers connected to each antenna connector, either directly if feasible, or using a very short piece of coax.

Doing so, the receive system signal-to-noise ratio would be set by the preamplifiers and not influenced by any loss occurring after them. So you could combine the two preamplifier output signals fully disregarding the impedance issue. You must only make sure that the two coax lengths joining the preamplifiers to the summation point are of identical length (whatever it is), so that the two signals get summed in phase. You could even use small coaxial cables (e.g. RG-58 or perhaps even RG-174 depending on length) that can be very easily handled, as any attenuation after the preamplifiers will not influence the receive system noise figure (within certain limits).

The above arrangement would be OK if using two antennas having the same polarization. But reading your post it seems to me that this is not the case. As a matter of fact, if I understood it correctly:

- you wish to mount one antenna on horizontal polarization and the other one on vertical polarization
- your objective is to receive a linearly polarized signal with a randomly slanted polarization plane.

If so, combining the two antennas using identical pieces of coax, you would obtain a system polarized on a 45-deg slanted plane, that would not help in receiving randomly polarized signals (signals that are orthogonal, or nearly so, to the antenna polarization plane would be strongly attenuated). You should instead aim at obtaining a circular polarization which causes a steady 3 dB loss independently of the signal polarization plane.

To do that you must introduce an extra 90-degree phase shift by adding a quarter-wavelength 50-ohm section to one of the two indentical-length 75-ohm coax pieces.

All this in theory. In practice I doubt that, at 900-MHz, a system like that would behave precisely as expected.

Regards.

In fact, this almost always NEVER happens. Skin effect defines the
layer depth of RF in ground. An 8 foot rod is like a splinter when
you are trying to harpoon a Blue Whale.

Ground rod engineering has been discussed in this forum to great depth
(pun intended, or not). The rods are as well understood as water
witching forks. In the HF region, single or several rods have no
practical RF use whatever. Above HF, absolutely no one gives them any
thought.

When you can't do anything else that is effective, a ground rod seems
like more than enough. It is certainly a need for safety's sake,
especially when your vertical could be a lightning magnet. Consider
that same antenna: is it directly GROUNDED? Or is it floating? If
ground is a panacea, I bet most of your advisors immediately isolate
their antenna from it. One has to wonder about faith....

Either design works with equal efficiency. You simply need a coupling
system to the grounded antenna design. One method is using a folded
monopole. Other methods abound (which are often confined to yagi
driven element discussion, but are eminently applicable here).

The Star system is great for exactly as you understand and describe it, but for antenna applications that remote ground could act as a suicide adapter if it does not have its own path to the service ground. Yes, this violates the star, but when path lengths include a lot of resistance and leakage current, voltages can become considerable when you supply a new avenue through your home. This is the story of the classic ground loop.

I'm not familiar with Dallas Lankford, but isolation and shielding techniques are topics I have visited professionally throughout the years and they are not simple. Without a concommitant discussion of the noise source, one wrong ground selection can wipe out all pursued benefits. Let's revisit one of your statements above:
>balanced microphone cable with a screen grounded at one end
Which end? Any choice stands an equal chance of being the wrong choice.

I have since visited your suggested page to casually view his works.
Interesting set of circuits too (although, some of the phasing systems
have been superceded with shift registers - I used to use
bucket-brigade chips).

I was especially touched to see wide coverage of the R390A. It was
the subject of my first class that I taught in the Navy (along with
the Collins URC-32). Cadillac equipment. I note in his discussion of
stabilizing the BFO, he uses a Rubidium standard for comparison. I
calibrated quite a few of those Rubidium standards too with my Cesium
Beam whenever a Boomer came along side. An URQ-12 would have worked
as easily, but this discussion no doubt exceeds the capacity of your
wallet (the Navy provided such a candy store for my Metrology Lab).

This is all good information and I can appreciate the difficulty of
creating the 75 ohm matchings sections due to the precision involved.
I have however found a power divider for this frequency that should do
what I need with respect to stacking the two yagis.

That is probably the easiest solution in this case.

C. Newport

True. I'm interested in using a single antenna for all of LW up to around 30
MHz as a simple starting point though, so Dallas Lankford's scheme seems to
fit the bill.

Safety is important, even though lightning strike isn't that big a risk here. Actually it's risen because nearly all large trees have been removed in the last two years, and I'd be held reponsible for any damage caused that way.

If you look at that PDF you'll see the 15' whip antenna is directly connected to ground through 80 turns of wire on a ferrite toroid. I might add a spark gap in parallel as that wire is not a high current path. So long as it is much more likely to go to ground rather than along the line in to the house, I'll have done what I'm supposed to do. The trouble would only exist (other than unpreventable natural excesses) if it were evident that I had not done this.

That PDF shows the coupling in this case. It's similar to other ideas recommended for similar small SW listening setups. Once I have all I need to try it I'm just as happy to try experimenting to see what happens as to try any plan. There are some limits though, the location is too built up to expect much from anything intended to be directional. I'm just intending to look around, not looking out there for something specific.

Well, a ground rod isn't going to cost much, and making and breaking connections to it is one of the easiest and cheapest things I'll be able to do, so I'll test that empirically when I'm ready. I won't try to predict it now. Whenever I find some new ground noise problem in anything I do here, I usually manage to isolate it and solve it acceptably within an hour or less, so I'll trust my chances. Usually the purpose hasn't been for RF, but quite often the sources did involve RF too so my instincts might help me more than my knowledge.

> Which end? Any choice stands an equal chance of being the wrong
> choice.
>

Well, I did think of that. :) And I didn't state it because I didn't know for sure. As I imagine that local RF couplings from various digital devices might place small currents on the local ground, I imagine that grounding a shield at the remote ground makes sense. Doesn't matter to me though. It's far easier and faster to experiment than to try to predict because there are only two ways to try. Dallas Lankford directly states that no shield is even required, and I doubt he'd have said that if he couldn't demonstrate it, and as that line is a two-wire loop that has no direct contact with anything, it should reject any common mode noise that hits it. Even in audio this matters because the same method is used to reject RF pickup on audio lines. I think some people persist in baluns instead of op-amp common mode rejection specs for this reason, despite the chances of modest distortion in audio bands from the transformers used. Not entirely relevant but it illustrates how people can find themselves choosing between two less-than-ideal circumstances for best effect.

I understand that noise context matters for a real attempt to plan for it, but that's far more difficult that presenting the basic antenna scheme.

Not just my wallet. :) This is cool though, I have encountered both bucket
brigade IC's and shift registers. Offtopic question: Did the bucket brigade
lead directly to the switched capacitor filter? I ask because they seem
related, and the BB seems to have become obsolete, but the SCF, anything but.

58. The Best Small Antennas For MW, LW, And SW by Dallas Lankford

Newsgroup: rec.radio.amateur.antenna

>The gain of the 15 foot noise reducing vertical is about -15 dB
reference:
http://www.kongsfjord.no/dl/Antennas/The%20Best%20Small%20Antennas%20For%20MW,%20LW,%20And%20SW%20rev%202.pdf

In a brief review of the article by the name found in the Subject line, I came across this bare quote offered above. It contains not one, but two unsupported claims that seem to be commonly encountered in the Short Wave Listening community.

The first that is more easily supported or denied is the gain claim of -15 dB. Where does this loss come from? Without any substantiation beyond the inference of comparison to "active antennas," it seems to be lost to indirect references in other writings. However arrived at, this claim is suspicious in the extreme - unless it is a vague and offhand substitution for antenna system gain which goes to the heart of the matter of a poor ground system. If so (the loss is found in the absence of an adequate counterpoise), that is indeed low hanging fruit that has been left rotting on the limb.

As for the noise reducing claim, this, too, appears to arrive through indirection or muddied with discussion of active systems. I can only surmise that the lowered noise was the noise of the added circuitry of the active antennas. If you discard the amps, I suppose you can claim you've improved the noise which brings us to the Gordian knot of the low gain needing those amplifiers - most curious writing.

>At least one person has claimed that noise reducing antennas are
>noisy. But when I quizzed him about his implementation,
>it turned out that he had not implemented the antenna correctly.
>If you do not follow the instructions,
>then you may end up with a noise increasing antenna like he did.

Good reporting would have described the defect so that the solution could be observed as rational rather than prescribed.

>much to my amazement, that long coax (50 feet) lead
>often degrades 2nd order intercepts of active
>whip antennas by 20 dB or more and degrades
>3rd order intercepts of active whip antennas by up to
>10 dB, depending on the type of active whip antenna.

It would appear that "depending on the type of" antenna begs the question why coax is the culprit. I can see how this kind of writing spawns a new superstition of the superiority of twin lead.

More could be said about Common Mode suppression (which the designs on this page do NOT entirely address).

Curious... You might have experiences that give useful insight into something I'm discussing in another group, some off-the-wall topic I entered into during a quiet new-year's moment in alt.lasers... I can accept that you might not want to get into that at all once you see it but if you do I welcome the input because as I state there, one issue is to find helpful signals rather than the noise such discussions usually provoke. But it might be a lengthy misdirection if you're busy so I won't push the point. But I will say now that my dad was a naval officer when he was younger and he SAW that thing I described right there with me, and he had no clue either. I just keep thinking that some people in the navy might be better able to explain it than most, especially if they have a strong science or engineering background.

Interesting. I guess fabrication accuracy and timing accuracy improvements led to its sharp cutoff and improved ability. I'm using one in some project I have on hold, a way to get pitched sounds to control MIDI signals for musical instrument control. I'll stop that line of thought there though, I'm not ready to go into that project for a while.

I don't know enough to query actual figures there, but I see the scheme as simple worth a try even without the amps. I've seen the term 'noise reducing' questioned, and I think rightly, but if it's just relative, if he has found the scheme to be less noisy than other schemes, he might just be using the term to indicate that. I do think the writing leaves gaps that should be filled, but again I figured that building it was easy to try. And I can always ask him, but I won't do that without setting up enough of it to test what I learn. Similarly I don't know any reason to assume the twin line is superior to coax. My provisional assumption is that its lack of direct contact with anything means that it probably isn't any worse. If it was, I think he'd have discovered that so obviously that he wouldn't be sticking his neck out like this.

Yes, it is a grounded design. The folded monopole is simpler, however
and you can deal with matching identically. 80 turns of wire on a
ferrite toroid is going to test the limits of self-resonance, poor Q,
and efficiency across so large a span of frequency.

Sounds like a lot of faith and work that will eventually require more
investment in faith and work. A shallow buried radial system would
puncture these superstitions.

That's why I tossed that hand grenade into the mix.

>As I imagine that local RF couplings from various digital devices might
>place small currents on the local ground, I imagine that grounding a shield
>at the remote ground makes sense.

It does, but that isn't the complete solution if you don't choke the
feedline. Again, ground is not found in the rod you drive into the
earth (which, by the way, will take years to "cure" to the ground

resistance you hope to achieve).

>Doesn't matter to me though. It's far
>easier and faster to experiment than to try to predict because there are only
>two ways to try.

This is about experience. You will find (and I have found) damn
little reference to grounding by connection to the earth. It has
taken me years to accumulate these rare references. They have been
topics of discussion here (use google to search the archives).

>Dallas Lankford directly states that no shield is even
>required, and I doubt he'd have said that if he couldn't demonstrate it, and
>as that line is a two-wire loop that has no direct contact with anything, it
>should reject any common mode noise that hits it.

Many people make direct statements (hard not to in this environment
that relies on textual postings). You need to find a better source of
study material as it relates to Common Mode. Twin line suffers it
equally. Again, all such discussion arrives through where the source
and load are, not in the line between.

>Even in audio this matters
>because the same method is used to reject RF pickup on audio lines. I think
>some people persist in baluns instead of op-amp common mode rejection specs
>for this reason, despite the chances of modest distortion in audio bands from
>the transformers used. Not entirely relevant but it illustrates how people
>can find themselves choosing between two less-than-ideal circumstances for
>best effect.

You are confusing topics here. BalUns and what are properly chokes
are not always the same, although their discussion is often co-mingled
to considerable misunderstanding. BalUns are NOT transformers as you
might imagine from the point of view of AF. It is regrettable that
BalUns are called transformers, as their full nomenclature is
Transmission Line Transformer - meaning the transform of Z by
transmission lines that have their ends isolated through choking
action.

Lest that sound too obtuse: The best BalUns do not operate through
magnetic flux linkage. You are not in Kansas anymore.

>I understand that noise context matters for a real attempt to plan for it,
>but that's far more difficult that presenting the basic antenna scheme.

Hence the novelty of individual threads. Noise arrives in the same
manner as RF - it is indistinguishable until you put on your
headphones. Noise is what arrives between your ears.

In regards to this last epithet, I noticed that Lankford wrote a piece
about quad detectors. I first designed one 40 years ago and the
critical component missing in Lankford's discussion (and probably from
many such discussions surrounding this method of detection) is that

the two channel output of a phase quadrature detector is meant to drive STEREO headphones so that the last step of detection is found in the brain's capacity to differentiate noise from signal.

Well, I'm not sure what you are trying to bring up here. As far as
I'm concerned, any topic is open for discussion. If others fume and
fulminate about this being an antenna group, I can easily turn the
discussion into one that is antenna specific.

What did your Dad see? (We used to joke that after the Pueblo
incident they put Marine guards outside of the radio shack for
security. If the ship was in danger of being boarded they were to
step into the shack and shoot the operators. Then I went into the
submarine navy, aboard a tender, the USS Holland, AS-32. We had an
escort sub that followed us at sea - to sink us if the Ruskies got too
close. Ah, the humor of those days.)

Ok, I'll definitely extend reaserch to cover folded monopoles. (Another
curious term given that there has to be some kind of polarity there, but
never mind..) I'll be making by own transformers and housings so I don't mind
plenty of messing around with those.

The yard out there is partially covered by most of the trunk of a large
felled lime tree, along with lots of branch logs, as part of an effort to
retain nutrients on land that is part of a limited strategy to preserve
wildlife in an urban district. Burying anything out there is harder work than
sinking a ground rod. :) I think I'm going to have to take my chances.

Even if I add a little salt water or dilute acid to accelerate that? This is something I've been considering.. By choking the feedline, do you mean placing ferrite slugs round it like those used on VDU cables? That's something else that will be cheap and easy to test empirically.

I'll do that. I gravited to Usenet for exactly this reason, I already collected a few rare sources of info this way in other matters. A lot of the best stuff is in web archives of usenet posts. (Although for audio I found a single magazine called Sound On Sound to deal with it efficiently. Not RF, but it's not exactly far removed technology). I think a lot of good references just never reached the net, except via postings by people who have read them. or if they have, they're in university archives I can't reach anyway.

There looks like one difference. Any signal hitting a coax screen if used in this scheme will have a corresponding return current in the core wire, but if there is any frequency dependent effect based on the nature of the coax braid's dimensions or in the difference between that and those of the core wire, then complexites beyond my ken might result (and maybe just as likely

be insignificant). The equality of nature in each half of a twin wire appeals to me, so long as it actually works. Should be cheap and easy to test that one...

Very likely I am missing plenty. Thing is, I see an unbalanced antenna-to-ground on one winding and an isolated and balanced line that loops back on itself carrying induced current from the other. It seems to me that balun and transformer are terms that apply equally there. In other words, it appears that the distinctions are neatly avoided while I am directed to exploit the common nature of the thing being used. Once I see if it works my interest will grow and I'll explore it further.

That's actually the single best argument for empirical testing. :) Something else that audio work has told me many times...

That's interesting. I've considered exploiting that idea before now. Not in much detail, just in principle because I've heard sounds that needed this to resolve them.

My aim is to find something in a practical situation that demands compromise.
Even if I learn all the principles I can't expect to apply an ideal, so I'm
looking for schemes that might save time in finding something that works for
me. They can't all be misses. At least this one consists of parts I can
easily reuse. :)

Antennas? In this case you'd have your work cut out for you. :) Wasn't just
him who saw it. I saw it first, for an hour and a half, before I decided it
would stick around long enough to justify getting my parents to look at it

too. I'm a bit embarrssed to mention it here other than to point to it there, but it was two crossed 'beams' in the sky. Trust me, it's hell of a misdirection if you're not up for it, you'd have to go to alt.lasers and take a shufti at the posts there.. But I agree, opening it to discussion is good. I spend about 99.999999% of the time keeping it to myself but I'm getting too old to want to leave it as unresolved as it is now. If it has to be, ok, but I ought to try..

Submarines? Those scare me. I never had to go in one, I don't know if claustrophobia would have beaten me. I have found the sound of water passing all round me as I waited for sleep in a crew cabin below decks in a ship's bow to be one of the most comforting sounds I ever knew, so maybe I wouldn't have.

Consider the significance of "shallow" inches, not feet; and sometimes
barely beneath the surface if you have to. If you don't have to (no
trip hazards to worry about) on the surface is equally suitable. You
don't need bare wire, but you can use it - it doesn't matter.

Radials need only be as long as your vertical is high. 16 to a couple
of dozen are sufficient.

>Even if I add a little salt water or dilute acid to accelerate that? This is

Don't go there. Curing takes years and is an issue of soil
compaction.

>By choking the feedline, do you mean
>placing ferrite slugs round it like those used on VDU cables? That's

That is exactly one very good solution. You need to research the
appropriate ferrite mix which is frequency specific when we are
talking about huge swaths of LF to HF coverage.

>There looks like one difference. Any signal hitting a coax screen if used in

This one statement exposes a very large problem in understanding about
the physics of coaxial cable.

Actually, it is harder than you might imagine at first glance. Yes,
the methods are simple, but getting past preconceived notions is the
single greatest hurdle. Many engineers are ill suited to the task.

I won't have scope for that much but I can certainly run a few longer ones on
unpaved ground alongside walls if that helps. I've thought about doing that
anyway.

Ok. I intend to use one of those drills that have a hammer action without
runing, to push the rod in. If I find a rod with a slight taper that would
help.

I will, I've already been looking into that so I don't have to blindly hunt
for some toroid by make and model number.. I notice the US has much easier
access to high permeability materials than the UK does, but no idea why this
is so. I saved a couple of PDF's with tables of frequency ranges vs materials

used.

Try me. All it needs is a clear statement that I can relate to something
I've already experienced. I'm well used to being cautious about what I learn.
Unless it's as tough as atomic physics, it should be digestible, even if
slowly. And I won't be able to taste it till tomorrow... got to sleep soon.
Thanks for this, it encourages me to take the time when others do.

The topic of model rocket telemetry communications was previously
covered in this thread:
<http://groups.google.com/group/rec.radio.amateur.antenna/browse_thread/thread/c158b265a04
1f9b6/>
While it doesn't answer your question about antenna stacking and
combining, it may offer some insight.

There was also this thread:
<http://groups.google.com/group/alt.internet.wireless/browse_thread/thread/108522ee8150506
9>
which involved model airplane control and tracking at 2.4GHz which
might be of interest.

Instead of this, why not use identical feedline lengths into a Tee and position one cross polarised antenna 0.25WL in front of the other, to obtain the 90-deg phase shift?

We shall proceed with a object lesson found in Fig. 5 of:
http://www.kongsfjord.no/dl/Amplifiers/Common%20Base%20Transformer%20Feedback%20Norton%20Amplifiers.pdf

Consider that this is described in the right side of Fig. 2 with all
the expectations of being "balanced." It is not. Even on viewing the
rough block diagram of Fig. 2 it is apparent in this lack of balance.
Fig. 5 and photos do nothing but support this shortfall.

At first glance, it seems as though these materials are classic text
book stuff that begs to be accepted as "balanced;" reality intrudes in
that RF (far more so than AF) finds interwinding capacitance is not
distributed equally for T2 and T3 primaries to secondaries.

The input/output windings are easily as unbalanced as one could find.
"Of Course! a protest might start. T2 is meant to support an
unbalanced input." However, a closer glance would admit that the
capacitive coupling from the top of T2 input to the top of T2 output
is NOT the same as the capacitive coupling from the bottom of T2 input
to the bottom of T2 output (irrespective of the implied ground
connecting, or not, to the middle of the T2 output winding).

The top Basic Amp is thus presented with a higher potential than the
lower Basic Amp. One might protest that this does not matter as T3
uncouples the two to present a new output through it to the 50 Ohm
output. My rejoinder would be "What practical advantage is then found
in the symmetry of upper/lower Basic Amps?" I would then point out
that the Common Modality present in the input, is amplified in the
upper half and finds its way through the system.

The solution involves complex winding taps with capacitors tied from
them to common to enforce a balance. This is not practiced

(obviously) in the object lesson presented at the page referenced above.

A protest might erupt that this example's capacitive asymmetry only admits of a very small imbalance. I would respond that Common Modalities may easily support considerable currents/voltages that when reduced through divider action are easily in excess of small signals of interest. The Basic Amp input Z is 50 Ohms; an imbalance in the interwinding coupling capacitance amounting to 50 KOhms will add 1000 microvolts for any 1V CM signal on the left. At 1MHz, this 50 KOhms would be a capacitance imbalance of 3 pF. Looking at the wire dressing of the coils in the photo would suggest 3 times this easily (and no attention has been paid to this at all). Now extrapolate to the 31 Meter band.... Could your AGC tolerate the local AM station's 10,000 microvolt leakage sitting on top of Radio Burundi's signal?

Grounding and shielding is not a simple topic although it is deceptive in appearance.

Doing as you propose is possible, and would produce the same circular polarization on the antenna boresight.

But moving away from the boresight, the circularity of polarization would degrade (into elliptical polarization) faster than if instead using a quarter-wavelength delay on one of the two feedlines.

So Richard, you seem to make vailed reports that something may be wrong
with someones ideas.
Why don't you make your own corrections with support and entirely address
all your ideas.
I figured with all the noise you put on the groups I would be able to find
a webpage showing all
the research you have done on antennas, amplifiers and receivers. I didn't
find your webpage, could
you post it so we can learn from all your properly supported research.
Thanks, Mike

That's the bit that seems most important, and I can also relate to it. It doesn't take much to cause a few pF difference.

A few points occur to me though...

First, to get it out of the way.. if this was causing serious bother, which it surely might if it is that bad at the lowest end of the SW range, what on earth induces a designer to persist in thinking it's working? Either it isn't, and he's deluded; or it is, so why?

Second, I imagined balance to pretty much relate to symmetry. I hadn't seen that file yet (even though I'd actually grabbed it with intent to), and the looseness of the coil wiring isn't lost on me. My idea was to omit the amps and just wind the toroids with neat symmetry to reduce obvious causes of imbalance and take it from there. If it works, I use it, if not, I try something else. Given that I have more than once been told that I might overdrive the input on the ATS-909 radio with a 18' whip in the back yard, I decided that I might as well omit the amps as they only boost a few dB, and instead rely initially on the built in attenuator for first efforts to see what's out there, then consider building (or getting lucky with on eBay) a preselecting filter on the input.

Third, the amount of effect a few pF has on a circuit would depend also on the inductance, or resistance, or any delay in the circuit. I hadn't looked closely at that (I'd want to see what happened with a simple test first), but I am guessing that the simpler idea of a twin wire with transformers and no amps would have a smaller risk of imbalanced signals, so a better common mode rejection. Why not do the amplification after the second transformer where balance is clearly irrelevant, if it has to be done at all?

I may still be missing something other than a grasp of quantities, but whatever I do, it has to be something that aims to do what that scheme was said to be able to do. I don't have a lot of space, and that radio ideally needs a single antenna to cover all of its AM range, at least for initial efforts. Ideally some scheme that can be improved rather than thrown out when I need something better.

Hoo boy, Mike, what you are asking for is a whole lot of research, not done by Richard, but done by some of the folks whose shoulders we stand on. Those are topics we all have access to.

This isn't a courtroom where people are asked the color of the sky, then asked if they have the meteorlogical or art degree at the pHD level, lest their answer be discarded. Get Terman, Get Kraus. Get Balanis, Get Best, If those are too rich for your blood,ARRL has some good antenna books, which are are more practical.

Interesting..
I just ran some NEC models with a pair of crossed dipoles. Two cases:
1) where the two are a quarter wave apart and fed in phase
2) where the two are in the same place and fed 1/4 wave apart

here's the axial ratios
angle spaced phased
0 0.99895 0.99373
5 0.99259 0.99173
10 0.9686 0.9774
15 0.92991 0.95122
20 0.87836 0.91519
25 0.81619 0.87053
30 0.74579 0.8185
35 0.66954 0.7604
40 0.58964 0.69752
45 0.50804 0.6311
50 0.4265 0.56226
55 0.34658 0.49196
60 0.26988 0.42098
65 0.19811 0.34989
70 0.13339 0.27906
75 0.07827 0.20868
80 0.03576 0.13878

85 0.00889 0.06928
90 0 0

Not a huge difference.. you have to be 45 degrees away before it's 10% different. If you were using directional antennas, the gain would be way down by the time you were that far off boresight, so it would be a non-issue.

I suspect that other factors would be bigger in importance.

That is answered rather simply: isolated experience. Having solved a
problem for single application does not make it a universal solution -
it is a good start however. For instance (as to this issue of
isolation), these designs were originally intended for lowfers where
this coupling would have been decimated (its impact reduced by 10).

Spinning out the same "successful" design to 10MHz without
consideration for this one issue I've pointed out would bring the user
to their knees: "I've tried everything and I still get this
interference!" Well, the user has not tried everything; it was simply
the right design in the wrong application which with a bit of effort
could be improved dramatically. Many of the layout and design
considerations for the lowfers are commendable and easily applicable
into the VHF. A VHF designer would have chosen other input topologies
is all.

In a sense, the VHF designer is also suspect for having an isolated
experience. Practical solutions are not always scaleable.

As I pointed out, very few changes are necessary and there is even a
simpler solution. You can shield the primaries from the secondaries
(kills the capacitive link). Unfortunately this brings a new problem:
where do you tie the new shield to? The wrong choice will actually
inflate the problem. As I said, this is not a simple field where
there are nesting layers of shields and broken shields with

non-contacting overlaps. Which one overlaps the other can bring
success or misery.

>Second, I imagined balance to pretty much relate to symmetry. I hadn't seen

>something else.

Well, here the topology you describe will carry the common mode
directly through (with some attenuation) as it is inherently out of
balance when the input primary's capacitive coupling is out of whack.
This is why I harp on "first principles." The amps have nothing to do
with the problem, they simply help illustrate the imbalance.

As to you "giving it a try" returns us to the heavily qualified
"success" of isolation. You could easily connect your antenna
barefoot to your receiver and experience no problems at all! This
does not constitute your "solution" as being universal. When you move
and try your "solution" again, it could easily fail for not observing
first principles.

However, this is not to impede you from simply getting on with it. The
hallmark of becoming successful is failing as many times as you can.

>Given that I have more than once been told that I might

Ham radio was invented on a bread board. You need one coil
(selectable) and two variable capacitors that can be scavenged from
very, very old table top radios. You would spend more in shipping for
a "preselector" than what you would pay at the nearest junk store for
these three items. Someone who had to pinch pennies would do it with
one cap and one coil and a lot of alligator jumpers. Even this
solution can be made elegant and occupy a space no larger than a
pocket sized notebook. If you robbed these componets from very, very
old transistor radios, you could build it in a mint tin.

You have barely nicked the surface of possibility in discussion here.
Loop antennas (which can be truly balanced and passed through coax)
are a natural answer for a lot of the spectrum you want to listen to.
In fact, "shielded loops" are explicitly coaxial and extremely simple
to construct (although many web sources describe them incorrectly).
They exhibit very sharp nulls (when that matters), and you can lay
them over 90 degrees to make them vertically polarized (and then use
them in phased configurations for beam steering).

My point is Richard constantly complains about others work, but I don't
see he has done any. I specifically was talking about anything he questions,
he
should support his rebuke and entirely address all aspects of the article.
He might know his shit, but all he does is complain, without support.

Hi Mike,

I should first help you with your search skills in finding my more
than 300 pages of antenna design for fractals alone. However, I am
not terribly concerned that they seem to be unavailable to the casual
search. Fractal design is a topic that has come and gone with no
apparent value discovered by Hams or Professionals as this field is
more a marketing issue. So, in that sense, your failure to stumble
across this mass of data comes at no particular loss - except for my
effort at that time. I sure didn't do it to bask in the glow of
appreciation.

As for more general antenna topics and your desire for a compendium
chronicling them - same advice: search skills in google for this group
will lead to more than 15000 offerings. I will leave it my
biographers to index them. ;-)

Going more broadly into technology, my career has spanned many, many
industries: from designing the flight recorders for the 747/757/767 to
metrology (most engineers have to look this up), to NIH research, to
pulp and paper chemistry, to A.I., to Web applications, to patents in
photonics, and on and on and on. I don't suppose you tried googling
the patent office did you? There should have been at least 5 hits
there.

Yes, this is beginning to sound like a drone. Art easily dismisses it all when he crows about my only degree being in English. Would you like to read one of my plays?

Hi Mike,

I think your problem goes beyond this demand for specifics, especially
when I have responded directly to every thing you say above in two
other threads that are current one of which relates to the named
author.

If you don't care for the subject matter in
"Matching impedance on 900 MHz Yagi stacking harness"
which I offer explicit answers
"The Best Small Antennas For MW, LW, And SW by Dallas Lankford"
which is very explicit (you don't comment to those points I've made,
do you?) and supported by other examples offered in:
"Sangean ATS-909 external antenna impedance"
to which I have done a very detailed circuit analysis;
then your complaint is very far from the technical discussion.

****

So, this must be about rhetoric. I like rhetoric. I enjoy irony -
especially when someone complains about the lack of content and who
then offers no content of their own. I enjoy semantics:
> I specifically was talking about anything he questions,
where I wonder what is specific about "anything?" This, of course,
returns me to the appreciation of irony because I am questioning, and
that must be what you are specifically talking about.

Imagine a newsgroup without questions: Arthurs spitting a tempest
with fascinated listeners all sitting upwind. Art would pay the price
of his dry cleaning ten times over for that audience.

Thanks, it is. I read the first part that covered the way RF current can flow on the outside of a coax, and how the same effect (though as you say, hard to visualise) occurs in a twin feed line. I see how it applies to the ferrite 'slugs' I shall try once I set something up, though I skipped most of the stuff on the voltage balun. The current balun made more sense to me right away.

Note that the idea that has caught my attention is to use transformers.. there would be no direct current contact between either the line and the antenna, or the line and the receiver. This isn't my own idea, it's just a wheeze that looks most interesting because it looks like it ought to work, and if it does it certainly pretects the receiver input rather well. It's beginning to look as if choosing coax or twin line isn't so important as knowing if that transformer scheme is valid, so long as I do something to block common mode currents with a choke balun on the line.

Trying to keep my post size down...
Ok, I see that isolated experience can be a problem. As far as I can see there will be a level of complexity best averted by empirical testing, so long as I don't miss something really fundamental. Which I am trying not to do.. I found a USMC guide to RF and antenna selection, a 5MB PDF file, that has a Marine's habit of cutting to the chase, it looks like I found a good guide there.
http://www.armymars.net/ArmyMARS/Antennas/Resources/usmc-antenna-hb.pdf

The topolgy I describe WILL carry imbalance through, I know. :) I thought it might at least be a start if it didn't add any of its own. I realise you were using the amps as an illustration of how imbalance can arise between those toroids, I was thinking that fewer parts means less to go wrong. Precise symmetry in topology might be a lot easier if I didn't have to use those. Again, I wonder why they're even there. Isn't it easier to put a gain stage after the second toroid?

Point taken on the costs of the selector. It was a long time ago, but I think I saw something intended to do this task, a design that built it from wire wound on a bit of plastic water pipe or something. I started Googling for designs earlier but got waylaid. One bit of waylaying involved a remark that tuning might offer more problems that a fixed narrowband filter, but so little context was offered that I don't know how to judge the remark.

If I put up conspicuous loops here I might get people bothering me about planning permission or some other means of negative compulsion. :) If I can do this with a vertical whip it will be much less awkward.

A circuit serves more purposes than gain. Of course, the simple
circuitry found in the file we are discussing has limited offerings.
Of what is offered is controlling input and output Z which is not a
trivial matter.

My preference is found in using Operational Amplifiers instead of
discrete transistors. There is more design flexibility and more
purposes may be served. OpAmps will control input and output Z with
far more rigidity (it is very difficult for externalities to shift
these parameters making for a rock solid design). OpAmps will also
preserve fidelity (faithful phase, magnitude) and not introduce any
distortion, and will drive out noise not already in the signal. Other
advantages can be obtained, but this is enough.

>If I put up conspicuous loops here I might get people bothering me about

Practicality needs to be served too. Loops can be useful indoors as
well, and they needn't fill a room. They will test the limits of
balance with the nearby clutter - an opportunity to turn your
environment into an RF lab.

I agree that, with a high gain antennas, it makes almost no difference at angles within the antenna main lobe. I could make more difference with regard to the susceptibility to strong interfering signals coming far away from the boresight, but this may be quite a theoretical case.

It could be more important in the case of two crossed dipoles (turnstile) typically used with low-orbiting satellites, but even in that case differences may be hardly noticeable.

In any case it is good to keep that in mind.

An ideal transformer will effect perfect current balance. What I don't know, and have never seen any theoretical or experimental work on, is how effective a real physical transformer can be made to be in that regard. There will be capacitive coupling between windings which could be a source of common mode current (current imbalance), and it might be necessary to take some or a lot of care in the winding to maintain good balance. And of course the system will have the windings' impedance between the conductors, necessitating care in transformer design for that reason. A fundamental advantage of the balun type connection is that the balance improves as the winding coupling becomes more intimate, while that tends to work against a conventional transformer. It would be an interesting study -- I regret I don't have the time to dig into it more.

I'll give it a go, though I don't know if what I try will have enough rigour
to give useful results back. I just sent a cheque for some FT114-43 toroids
which are big enough to consider a screen between windings, though as Richard
Clarke said, it might be awkward finding the best point to tie that screen
to. Re impedance of windings, I have no idea or plan except to aim for close
spacing (within each coil) and neat symmetry, and glue to keep them in place
so that whatever results it remains steady.

I really like op-amps too, they have often made my life easier. Not used them
in RF though, just audio and modest DC instrumentation designs of my own..

About those amps in that scheme, I think I didn't grasp what they were doing,
other than gain, because I assumed the idea of balancing implied by the
design would be central whether they were used or not. It still seems to me
that if the line worked without them, then a single stage could be applied
after the signal passed to the unbalanced input after the second toroid. If
not (as in not possible as opposed to merely awkward), then I'm still missing
something.

I'll definitely read up on loops. (Been reading the first of two USMC radio handbooks today, second is an update of the one I found yesterday. No loops mentioned in first, but the second is specific to antennas. Both guides are quickly filling forgotten gaps in what I knew, plus showing me plenty I didn't).

Btw, how critical is the resistance of wire in a few ground radials? I have some thin stainless steel wire that would be strong and enduring out there but at around 1.5 ohms or more per 6 inches I can't help thinking that's too much. I like the idea though, because clamping ends of it very firmly between copper washers could be fast and easy for good and reliable contact.

The stainless steel is a non-starter. Use more radials of wire-wrap
wire if you are concerned about visibility vs. thickness.
Vegetation/grass will quickly bury most wire when Spring comes (and
possibly before). Grass will be so tenacious that even mowing the
lawn will not bring it up (unless you have a thatching attachment).

Ok, copper's no problem, was just wondering about stuff I had plenty of at hand.. I wish I had a lawn. :) I was thinking that it would be an ideal method. My main difficulty (apart from a large amount of heavy logs (and most of a tree trunk) is that the best place to mount the antenna is in a far coner of a plot so I can't lay radials all round it. I can probably get the permission of one neighbour to run a ground wire along the far end of his garden along a low wall, but that same wall is a high wall on the other side, there's a drop of several feet as well as no chance of permission to lay wires there. This is why I'll want a ground rod, as a tree used to grow there, the rotted roots might be my best chance of anything like a conductive network that is close to the surface, in addition to a few ground wires. I'm a tenant, I don't own the land, and can't do much except work round what is there.

Thinking about what I read recently, it seems that if the whip is not
vertical but slightly leaning back over the plot of land toward the houses,
it will have a better chance of using the sky waves, but what I don't know is
whether that demands ground radials to be biased (if biased at all) to favour

coverage on the side the antenna is leaning over, or the other side. My guess is the side it's leaning over... Is this true? If so, it will help a lot to make the best of that space.

Ahh, I was being a little facetious anyhow. THe American Association of English majors is a fictional association created by Garrison Keillor of Prarie Home Companion fame. He makes fun of English majors - of which he is one. He has a couple other groups too, like the Ketchup Advisory Board, and the American Duct Tape Council.

I was just pulling your leg, IOW.

Running a fan of 90 degrees is fine, there's nothing exact about this
except for those who imagine they will suffer the dB of
out-of-symmetry.

>> I can probably get the permission of one neighbour to run a ground wire

Don't bother. It isn't worth anyone's effort or intrusion.

>>This is why I'll want a
>> ground rod, as a tree used to grow there, the rotted roots might be my

A wire mesh or mat (like chicken coop wire) over the surface of that
area would serve far better. That doesn't sound like an option so the
matter of pursuing conductivity of rotted roots is an illusion.

>>I'm a tenant, I don't own
>> the land, and can't do much except work round what is there.

You'll be able to do enough without much impact.

Your gain/loss advantage will be in the direction from the antenna
base out along of the middle radial in a 90 degree fan. Leaning won't
significantly alter things for a very short antenna (in terms of
wavelength).

Now as to these advantages and disadvantages. Once you get to a minimun set of radials (call it four), the addition of more wire won't budge your S-Meter more than a needle width (and that is being generous). The addition of more radials concerns establishing a firm reference of ground for Z.

On the subject of particle wave duality with respect to radiation, I
pointed out to several physics forums that
the gaussian law on statics is the same as that of a Faraday shield
and when applied with a time varying field amounted to radiation per
Maxwells laws. Both of these instances suggests particles with spin,
probably helical.
Now physics forums have moderators with the power to ban questions
that challenge existing laws (waves) where as the questions and the
poster can be censored and banned.
This, of course, has happened to me. Reading further I see that
physicists are plagued with "crackpots" mainly "engineers" who come up
with theories that challenge fully accepted theories made by
physicists with many years of math study that cannot be equaled by
others!
Since the particle has spin of helical form it makes me wonder if the
helical action is what is referred to as a wave, but no answer is
available which is also followed up by banning. (lack of mathematical
reasoning)
We do not have moderators on this newsgroup, but just imagine how a
few can determine the incorrectness of radiation or challenges to
accepted science could stifle
the whole idea of experimentation in our hobby and hold of progression
within the hobby!
Forums are not perfect by any means but the idea of moderators that
can ban or censor free thought where only questions accepted are those
that can be answered parrot fashion from the books just throws me for
a loop. I know that censorship exists in many countries which are
controlled by a few or a committee
I sure hope that anything like physics censorship is not bestowed on
this newsgroup. by moderators with brains of a higher calibre than
those that post.
Looking at how progress is defined by the Nobel prize
I see that nominies can only be accepted by those "known" in the
field. In other words, the poll of insiders
make the choice. The nominees are then adjudicated by a committee of a
dozen or so (connected to the funds side) who then decide the winner.
The bottom line is that the winner is determined by a group that wish
to continue being thought as an insider or equivalent scientist by
coat tailing a winner.
Obviously we are still accepting that "all is known" in the sciences.
But then, why do students have to buy those new expensive books each
year if change has not come about?

Thankyou. This is good, it sounds like the basic plan will work then, and I might be able to get some chicken wire to cover at least part of it. One possible complication I didn't mention is that the intended mounting point is at a T junction of three wire mesh fences of equal height, about 6'. They don't have very reliable conductivity between each zigzag strand (oriented vertical) as at least one fence has a green plastic coating on its wires. I intend mounting the whip on a concrete post at the junction of these fences. I imagine the fences will raise (and make diffuse) the precise physical level of the RF ground, but I don't know whether they'll be a serious problem, or maybe even be helpful. I can try grounding them a bit better, but otherwise there's not a lot I can do about them.

One other thought... In that USMC antenna manual there is a mention of something similar, a 15' whip tilted and also tied back so the upper part is almost horizonatal, it's intended as a way to use short(ish) distances for skywave propagation. It looks useful given the context of trees and buildings within 100m of my best mounting point. What I'm not sure of is whether the curvature of their tied antenna is relevant, or a straight tilted whip would have no significant differences.

Or look to a simple physical aspect and call it inertia. Whatever it is, if you agonise over it you won't do much about it. I sympathise over this, I dislike the way patent and establishment turns technocracy into preisthood, but it still boils down to what you acheive. We might live in a world where current doctrine tells us that all is ruled by chance and that science cannot look into all things as some things must be permantly uncertain. That's fragmented not just science, but the whole of society because if no-one can validly seek a single truth many will just go seeking their own, hence a proliferantion of New Agey stuff, etc. But one thing doesn't change: Either a thing works or it doesn't. And never mind the maths, if it tries to predict too much, don't trust it. If it's descriptive of observations it might lead to new predictions, otherwise it might as well be an abstract model that can't predict anything. I don't know anything about what grounding you have, but it doesn't matter because this applies to all thought. If you have really found some new path, why try to force convergence with an old one? I'm staying with the old one because what it describes matches what I know, and I value its anchorage. Seems to me you either need to demonstrate an easy convergence of a very different theory so that anyone can reality-check it and still find it true, or build things based on it that verify predictions so others can see that happen.

I said this because it felt more right than not saying it, but I'm getting too old to go round in circles so if I find myself been drawn into any I won't go there. I wanted to stay silent on this, but however strange your ideas seem to me, there is something I can sympathise with about the trouble they cause for you. Sometimes if the roads don't join, you just have to keep driving on the one you're on.

Or in other words you attempted to post a bunch of ramblings about
"helical waves" without any results or math and expected them to spoon
feed you the contents of generally available texts such as "QED: The
Strange Theory of Light and Matter" by Richard Feynman.

Chicken wire rusts out pretty fast.. You'd probably be better off just
scrounging some AWG20 copper wire and improvising a little grid or
randomly laying it out.

One

Curvature isn't "significant", and for a lot of cases, the tilt isn't
either. But, tying the whip back does keep it from whacking too hard on
low hanging branches.

Suit yourself. It was he who used the words "nonsense, ramblings"
etc so I threw them back and will always do that. Now you bestow the
word "idiot" what should I say in return? For years he has slandered
me, just look at his record in the archives. Like many others who are
now getting old they seem to magnify their accomplishments and the
promotions they should have got for their endevours in life that some,
on the West Coast that is, suggest that they can see Russia from their
homes just to impress. So now you have become a judge with outstanding
qualities, O my! Don't often see people like you in East London as far
as I can remember, at least not for long.
As for science, all on this group say it is illegal to add a time
varying field to a static field to make it dynamic ,which equates to
Maxwells equations. If you don't agree with them then they have the
license to slam you. Good grief That is their standard on science that
they align with.

```

> observations and conclusions to Faraday, Gauss, Maxwell and others?

With Maxwell's equations, which are a set of four partial differential equations that relate the electric and magnetic fields to their sources, charge density and current density.

With Gauss's flux theorem, which is a law relating the distribution of electric charge to the resulting electric field.

With Faraday's law of induction which relates the induced electromotive force in a closed circuit to the time rate of change of the magnetic flux through the circuit.

However, you can't with arm waving rambling.

<snip rambling>

I have never in my life been a lab technition (sic).

<snip rambling>

> You, yourself, have a long experience as a technician

You have no clue what experience I have.

<snip rambling>

If you want to know why your rambling nonsense is rambling nonsense, read an elementry electromagnetic text such as "Electromagnetics" by Kraus and Carver.

Yeah, I know, hundreds of thousands of people who have studied the subject for over a hundred years are all wrong while you have the "Truth" in magic bouncing particles.

>
> You have no clue what experience I have.
O yes I do, I read your postings in the archives to understand what
level you are.
>
> <snip rambling>
>
> If you want to know why your rambling nonsense is rambling nonsense, read
> an elementry electromagnetic text such as "Electromagnetics" by Kraus
> and Carver.
You mention Kraus who spent a lot of time messing with radiators that
were not in equilibrium. He was bound to the idea of waves that
cancel, where if he had considered particles his helix radiators would
be in the form of a closed circuit such as a ribbon line where
particle vectors are additive. His work on helix antennas are so
incomplete
since he does not account for all forces involved for radiation.
Faraday shield is an excellent example of this where provision is made
for displacement current to contain a static field. I have an example
of that on my page Unwin antennas where I specifically state the
rudiments of current flow. As yet nobody has supplied scientific data
to show that flow is otherwise. Thru out the ages it has been
understood that the datum line for the laws of physics is the state of

equilibrium such that all forces are accounted for. For radio this
requires the use of radiators of a full wavelength which supplies
equilibrium and resoinance. Yet for some reason many including Kraus
has rejected this undeniable fact, Thus when applying Maxwells
equations they can never attain 100 percent efficiency. This can ONLY
be attained when an array is resonant and in equilibrium as must be
the individual radiators that consist same. On top of that, there is
no reason that a radiator should be straight only that it is in a
state of equilibrium. Think about it in terms of boundary laws that
abide with the laws of Newton in every aspect. Model a ribbon helix
in equilibrium or a simple helix antenna of Krauss and compare which
is the best for yourself instead of being just a follower. Look up
Faraday shields on the web and determine how electric fields and
magnetic fields are cancelled thus leaving just a time vary current
that your receiver can use. Think about how you can accellerate a
charge when it is just a field without mass and acts as a wave Use
your brain if you have one.
Your quotation of Maxwells laws does not impress me one bit as you
obviously do not know how to use it because of the lack of
understanding.

>
> Yeah, I know, hundreds of thousands of people who have studied the subject
> for over a hundred years are all wrong while you have the "Truth" in

No, not all, a Iot is very much disputed outside this group

No, it is not my truths! It is those of the masters which are now
largely ignored by computer operators and the present day crop of
physicists
who now rely on probability mathematics as the proof of the truth.
And why do you think that Feyman described duality as a"strange
theory" which is based solely on the incorrect analysis of an
experiment that does not jive with those of the Masters?
Frankly, you are not much of a judge with respect to physics.

>at a T junction of three wire mesh fences of equal height, about 6'. They
>don't have very reliable conductivity between each zigzag strand (oriented
>vertical) as at least one fence has a green plastic coating on its wires.

Both the mesh of chicken wire, and the fence crosspoints may suffer
from cross-modulation products due to corrosion at the joints AND if
the metal is galvanized. This is evidenced in a nearby transmitter
(and nearby is relative measure) exciting the wire, and rectifying at
the corroded crosspoints. This rectification creates harmonics and
you are off to the races in terms of spurious frequency generation
across a wide bandwidth.

Oh Brave New World of common mode.

>there's not a lot I can do about them.

As you describe at least one fence having insulated wire (which is
good from the cross-mod point of view) this makes no difference RF
ground-wise; and being elevated only slightly shifts things.

One exception is found in proximity in that this elevated ground will
indirectly short out the lower section of your vertical. This is more
a matter of Z than sensitivity.

The solution is to elevate your vertical's feedpoint to the height of
the fence top.

>One other thought... In that USMC antenna manual there is a mention of

>have no significant differences.

Well, what they (or you) call sky wave is properly NVIS (near vertical incident _____ - I forget the last part) which is meant for local communications, which is more what the ground forces are interested in. The Marines in Afghanistan are not going to DX headquarters back at Pennsylvania Avenue in DC. When I taught VHF/UHF comm in the Navy, our equipement easily lost 10dB of transmitted/received signal levels just getting from the shack to the antenna. We didn't care. Push more power if necessary, as for reception, line of sight was all that was necessary, and that was to the horizon (no more than 8 or 10 miles). I don't think the government has bought any QRP rigs since WWII.

In fact, that tilting's mission has also been satisfied with end loaded dipoles place directly on the ground (which was largely sand). I and my buddy used one for field day. Another antenna is an unterminated coax laid across the ground. Both suffer mightily in efficiency, but they offer ease of construction and purport to enjoy less noise problems. To this last, most local noise arrives by vertical polarization, and signals in the sky arrive by elliptical (both vertical and horizontal by varying degree) polarization. For a quick and dirty test, I doubt any other test could be quicker to do. You might want to add a short pig-tail to the unterminated coax.

Further experimentation would be to add 8 to 10 inches of ferrite beads to the coax, half way back on it toward your shack. This would snub your home's injection of noise into your receiver (conducting out from the house on the coax outer shield and folding back at the far end). The next experiment (if this first proved useful) would be to add a local ground at the same point and tie it to the shield (after penetrating the jacket, of course). Yes, this violates some of my other advice about mixing grounds, but for experiment's sake, it will add to your repertoire of learning the complexities and benefits of ground. The purpose of this new ground is to discharge that choked noise into ground. I have successfully done this to quiet my home's noise generation as detected in my receivers. The ultimate proof of this concept is being able to throw the master breaker on your home and noting any change in the noise floor.

Throwing that breaker is probably at the extreme of your family's tolerance of your hobby. To this end you want to plan to do it once. This means doing a noise floor survey at hourly intervals for all bands and keeping notes for a week or two. Then, one day when there's the least possibility of disrupting domestic tranquility, throw the main and do a quick survey again. I have managed to quiet my receivers by 5 to 10 dB through tests like these.

Buried cable, or ground level run cable can snub local noise induction too (but it is still a good idea to choke at the feed point if no where else). This last observation is to inform you that metallic

connection to earth is not always necessary. You should be equally informed that the proximity of earth can also negatively affect what positive gains you are seeking too.

True. Was just thinking that it's not that hard to find something meshlike so
even if it did it could be replaced for free. Given the price of scrap
copper, that rarely comes free these days. :)

>

In the case of a 15' whip, tilt might be. At least, if it isn't I have to
wonder why that USMC antenna manual was suggesting one for short-range
skywave use.
Document is "MCRP 3-40.3c" (PDF) 'Figure 4-34. AN/MRC-138 with NVIS Antenna'.
(About 4/7 of the way through that file, as gauged by scrollbar).

Where I am it seems the best chance due to surrounding buildings, trees,
fences, etc, is to use a slightly less exaggeratedly steep 'view' of the sky
than is implied by that description and drawing. If you look at that drawing
you can see that it isn't done to tie the antenna out of the way. :) There
seems to be specific reason for doing what they do there.

The curvature made me wonder, based on a relector, in an indirect way... I
read that a longer straight isolated rod placed directly behind a whip,
separated by a quarter wavelength, could be a reflector. While I guess any

curvature in either that rod or the whip might be insignificant at low HF, I inferred that it had to be straight to work efficiently if the whip was straight. There seemed to be implications that straightness, or lack of it, mattered. That made me wonder if curvature in a whip (forget the reflector, I have...) leaning toward a building might very slightly favour pickup on the convex side and attenuation on the concave side, or have any other mildly directional benefits. If so it might be a useful part of a strategy to reduce noise from nearby buildings. Of course it might be useless trying, but it looks like a nice idea...

Hmm. :) Just going to have to chance that, the bigger fence (main road in T
junction metaphor) is a galvanised type, with plenty of weathering. If I have
patience I might weave in a grounded length of copper wire, but I suspect
more weathering will nullify any useful initial results of that move so I
probably won't.

Oh, it will be. A tad higher, if anything. Just a few inches though, between bottom end of whip and top of fence.

I don't have a lot of line of sight.. While I'm not living in a well, that might be a closer analogy than the terrain most SWL'ers assume they'll find. I do get a fair chunk of south and western sky though. I figured a scheme intended to transmit to such a space should receive ok from it. If I try any other angle I might as well try to hear the local neighbourhood noises, but getting a sense of what lies beyond all that is why I'm doing this. Maybe after some initial tries I might have to consider something much more directional anyway, but hopefully not.

An odd idea, but I like it. It might be that in my location some drastic shifts from convention, to get best SNR never mind losses, then add gain later, might be best. If something like that worked I'd leave it working.

Ok, I'll be keeping the feed line as mobile as I can, because I already suspected that position and number of ferrite slugs might be something I want to change a lot to test. Ultimately I hope I can run it along the top of one of the chainlink fences. Circuit breakers will be no problem, I live alone in a basement flat. :)

Message-ID: <luGdnTr8f9fG3tjWnZ2dnUVZ8vidnZ2d@bt.com>
Source record: 11274

<snip>
I have an example
of that on my page Unwin antennas where I specifically state the
rudiments of current flow. As yet nobody has supplied scientific data
to show that flow is otherwise. Thru out the ages it has been
understood that the datum line for the laws of physics is the state of
equilibrium such that all forces are accounted for. For radio this
requires the use of radiators of a full wavelength which supplies
equilibrium and resoinance. Yet for some reason many including Kraus
has rejected this undeniable fact, Thus when applying Maxwells
equations they can never attain 100 percent efficiency. This can ONLY
be attained when an array is resonant and in equilibrium as must be
the individual radiators that consist same. On top of that, there is
no reason that a radiator should be straight only that it is in a
state of equilibrium. <snip>

Art,

I think this paragraph may be one of the reasons for all the protests. It isn't necessary to achieve 100% efficiency or to use a full wavelength radiator in order to broadcast (or receive) a radio signal. It may be desirable, but it isn't necessary. Modern equipment has sufficient power to overcome the inefficiencies when transmitting and can hear signals well below the noise floor when receiving. A 50% efficient antenna is fine for most applications and perhaps 10% or less will do at a pinch.

The patent office floors are littered with designs for better, more effective mousetraps, but that 99 cent (pence) bit of wood with a powerful spring will kill mice just as dead. :-)

The particle wave duality of electromagnetic waves was settled back in the 1930's and further refinements have only gone on to prove that electromagnetic waves act as both particles and waves depending on circumstances and measurement. There is nothing wrong in considering the generation of an electromagnetic wave using particles, so long as the end results are in agreement with measurements taken using standard scientific equipment.

If your antenna calculations show 100% power transfer to the antenna and 100% power radiated, then that should be capable of being substantiated by standard measuring techniques in the near and far fields.

If your antenna only shows these readings when a similar receiving antenna is used and attached to the measuring equipment (rather than a standard dipole) then you have either invented an entirely new field of physics, or the calculations are wrong.

I'm sure your compact antennas do perform better than others contained within similar physical dimensions. A full wavelength resonant radiator must theoretically be better than a fractional or loaded system. But proving that it is worthwhile, better and more convenient to Joe Public is a much harder sell. Your ideas about particles might be correct, but do they give a better understanding and predictions of antenna behaviour than the currently accepted theories? In order to succeed, I would suggest that your theory would need to match all current observations but then go on to make some new predictions about antennas which can be measured and verified. That is the way that western science has progressed since the Greek philosophers tried to explain the world around them. Some Asian cultures are allegedly more amenable to accepting that some things in the world are just the way they are and require less stringent proof. It allowed them to leapfrog the West and make significant practical developments of everyday useful stuff without worrying about how it all worked exactly. The only problem with this approach is that if you hit a wall in development, it usually isn't clear how to make further improvements or solve the problem except by trial and error.

Keep up the good work.

Regards

Mike G0ULI

Also agreed with except for radio waves that if duality over the whole
spectrum is true it is not so with radio frequencies. Gauss makes it
quite clear that static particles can become a dynamic field

according to Maxwells equations. If they become waves at the higher
end of the frequency span say beyond X rays it is of no concern to the
subject of radiation in the amateur bands which is the field that I am
working with.

>
> If your antenna calculations show 100% power transfer to the antenna and

Quite true

>
> If your antenna only shows these readings when a similar receiving antenna
> is used and attached to the measuring equipment (rather than a standard
> dipole) then you have either invented an entirely new field of physics, or
> the calculations are wrong.

I dont see it that way since a 4 ft dia mesh has many WL of wire
contained for top band so it should be able to choose its own route
for
a particular frequency resonance. The more WL you have the more likely
resonance would occur.
>
> I'm sure your compact antennas do perform better than others contained
> within similar physical dimensions. A full wavelength resonant radiator must
> theoretically be better than a fractional or loaded system.
On my page I show instances of resonance using 6 inch samples of
mesh which match the amateur bands so i see it as a huge step with
respect to small radiators. also pundits state there is a need for
smaller broadcast antennas(cross field) without ground plain.
I personally see the advantage of double the skip distance even when
ground situated. Military would see similar advantages. I see the
confusion as purely my position that with respect to radio we simply
have particles without evidence of waves and the fact that from a
specific rule point equilibrium exists only at the period point and
not 1/2WL. It is the recognition of this mathematical point that
allows
both resonance and equiulibrium which allows for compression. To use a
1/2 wl is a violation of the universal rule, simple as that.

But proving that
> it is worthwhile, better and more convenient to Joe Public is a much harder
> sell.

That is true but if there really is a true need for a technology for
smaller volume radiators together with human shielding protection to
go along side present miniaturization, then it will sell itself.

Your ideas about particles might be correct, but do they give a
better
> understanding and predictions of antenna behaviour than the currently

> how to make further improvements or solve the problem except by trial and
> error.

Yes, that is always true but I see as significant is that radiation
can now be shielded when used and is not automatically sky wave at
ground level and, ofcourse, that it is small. The old adage of putting
up as much wire that you can is neatly solved with mesh while staying
in equilibrium. What more can you want?
How many questions do we see for an antenna without room for a ground
plain? How many questions do we get for a broad band scanner antenna.
How can a submarine transmitt with out detection trailing a humoungos
radiator where the wash is seen for miles?
How can we prevent moon dust from contaminating rockets. It just
doesn't stop.
When you can transmit from ground level without height interference to
TOA you are effectively doubling the range for the same power.
On top of that the public is easily convinced of its use when the
advertisers state that damage to the brain cannot now possibly occur
because of shielding.
It just blows my mind that amateurs have lost interest in new antenna
design based purely on a mob that denies the possibility that it
cannot work without stating why.As for me I have no more need for a
tower.
Best regards
Art Unwin
The PTO did not turn down my response to questions regarding the first
patent application so I assume it will be awarded in good time.

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team. We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

rec.radio.amateur.antenna |
rec.radio.amateur.boatanchors |
rec.radio.amateur.dx |
rec.radio.amateur.equipment |
rec.radio.amateur.homebrew |
rec.radio.amateur.moderated |
rec.radio.amateur.space |

We are willing to provide any technical support necessary to get this
article updated and automatically posted again at a regular interval.
This would include establishing contact with the original maintainer for
any necessary permissions. We would prefer to seek a new, dedicated
maintainer at this time, rather than start auto-posting the original
article ourselves.

For more information about our newsgroup, see:
```

there is no exception for radio waves, they act as photon particles
also, just like the ones at visible light frequencies and higher. this
too has been accepted for many years.

It is impossible to read what you have stated. Has anyone seen your
antennas, you old fraud?

David, I won't fight you but I would like to take advantage of your
expertise. The question whether you may make a gaussian field dynamic
such that Maxwells equations can be used is the beginning of this saga
as the group will not accept it.
So I will move on to the Faraday cage.
There is an animation of what exactly happens on the web with respect
to radio, you may want to look it up.
But for openers you would get my attention in explaning this phenomina
with the use of waves instead of the actions of mass or a particle.
This is a sincere request as it seems discussion of duallity means
talking past each other when there is a clear difference between the
action of waves and those of particles,namely attraction. versus
cancellation.
You supplying this may get the subject back to a level plane of
politeness where the postings will supply enlightment instead of
derision.
Thanks for reading

Art

You are an idiot.

Bill,

A trifle blunt and rather harsh. It's an analogy. The sun is producing heat
by fusion rather than burning, but particles are thrown out from the solar
surface in the solar wind and coronal mass ejections. Art has been pursuing
his theory for years. It's one of the largest postings in the newsgroup.

Mike
It doesn't bother me what he says unless he addresses the subject.
If I am wrong then I want to know why not to fight which is what he
wants.
I suppose we could ask for an explanation as to how a capacitor works
since it seems to me that it does exactly the same as a Faraday shield
or a Gaussian circle. I wouldn't mind dissent as long as they explain
why. Yes, it has been years that this discussion has gone on and
Richard and others have taken the position from the outset that
a Gaussian circle can have no connection to radiation, but refuse to
provide the reasons why this is so. Of course, if he is in error it is
natural that he would like the subject to go away, if he is correct
then he can easily accomplish what he wants. He does have choices.
There is no doubt that he has his followers who are calling me
stupid ,

idiot etc and possibly want me to respond by calling them homosexual or maybe worse , but none of that gets me to the point that I am seeking. I have done the work or experiments and now we are at the point of interpretation as to why those results occur since this is the usual point that errors can be made. All simple stuff. Actually, Mike, it is like being on Hyde park corner where many bring a box to stand on and start preaching to the crowd. Why they do it I do not know since most people snicker and then move on.

duality applies to all frequencies of electromagnetic waves and photons... it all depends on which is more useful for whatever you are working on. particle physicists like photons because they can draw them in feynman diagrams nicely and they like to talk about them getting absorbed and emitted by valence electrons, engineers generally prefer waves and fields because they are easy to calculate over macroscopic distances using maxwell's equations.

and i still say your extension of a time parameter in gauss's equation is unnecessary since the equation applies at all times. just because no 't' shows in the equation doesn't mean it is necessarily static, just that it is not an explicit function of time. actually if you study all 4 of maxwell's equations closely you will see that NONE of them are explicit functions of time. two of them do contain dervitives with respect to time, but none of them contains 't' as an independent variable.

One short point. Time is omitted because it is based on equilibrium
alone where nothing is happening and all is balanced The Big bang was
the instance that time began and equilibrium is broken by movement or
energy exchange. It is the energy exchange subject which alone gives
us the picture of change without which there is nothing.

David
Well that is a good opening or introduction, tho I wish you had not
mentioned your thought of adding time to Maxwell as the response to
that was explosive years ago. I hope that others will put that aside
so we can concentrate on the main thrust of the problem.
I will be very interested in what you will use as the subject for
explanations to how the wave actually works. From the above, I really
believe you have the background or track record to explain all and how
things are working to the satisfaction of all. This could be exciting
Regards
Art

Yes, you are correct, as is the comment regarding the number of basic
colours. The introduction was meant to provide an outline to the
subject without getting involved in Lepton and Neutrinos that in the
past took away from the subject at hand namely, particles arriving
from outside the Gaussian circle. When the above items were introduced
on this newsgroup a lot of bad names went flying about, but there was
one comment that stated, for this group it would be better to stick to
particles than to speculate on the subject prior to entrance to the
Earth's circle. Using the term Leptons and the number of different
flavours or colour such as the three colours that are used in tv was
really a mistake when considering the audience I was hoping for. More
than 7K has viewed it according to QRZ but nobody siezed upon this to

make a complaint, but then one hopes that this group is more knowledgable My sole intent of introducing the Sun was to link the Suns rotation cycles to the hobby of ham radio as we see it as an introduction and not to generate a science paper otherwise intrusion into the subject of nuclear decay would also have to be introduced, and it goes on.

And showing more of his ignorance or lack of attention to detail, it
really doesn't matter which, he doesn't realize that fusion is not
nuclear decay.

Art should give it up, but he doesn't realize he's just flatass wrong
about almost everything he says, so he never will. Either that or he's
one of the nets most successful trolls. It matters little which.

Art would have us believe that objection to his abysmal ignorance is
in fact censorship. So his persistence makes him a martyr, you see.

no, time is omitted because it is irrelevant to an equation that
applies 'at each instant' in time. so at any instant you can add up
the charges inside the gaussian surface and know the total flux
through the surface. the only 'equilibrium' is the equals sign that
states that the total flux is equal to a function of the total
charge. you can indeed have energy flow across the gaussian surface
and the equals sign still applies at every instant in time.

but what is the 'problem'. maxwell's equations as published for the
last hundred years or more seem to work just fine to the limits of our
measurement capabilities.

> I will be very interested in what you will use as the subject for

> Regards
> Art

No one knows how the wave 'actually' works, but we have maxwell's equations to tell us how to accurately model and predict configuration of fields and the propagation of waves. That is the one thing your 'theory' seems to be missing, in order for you to have a theory worth discussing it must first be put down in equations that describe something measurable so it can be verified versus reality... AND then it must predict something different from all other existing laws and theories. without those two conditions you are just a handwaving carnival hawker trying to sell patent medicine to people who aren't sick.

I don't know (my Towers selector book is too old for that one, but I can copy out its specs for you if you need) but I crossposted this reply to sci.electronics.components where there's an increase in chance of a useful answer.

O.K David Let us look at the Faraday cage or better still a shield.
Faraday has shown that when one side is impinged upon by a ":wave"
that it will separate into two components of "waves or fields". They
will not stay as one but will separate into two separate energies or
charges
On one side of the conductor (electric field) and the other field
will follow (magnetic) on the other side of the conductor. The time
elapsed is equal to half a cycle or half a period of the frequency
applied.
During the next half cycle the charges as they are now on each side of
the conductor are drawn opposite to each other with the conductor
inbetween.
Thus this second half of the cycle of time is taken up by movement or
an accelleration of the charge inside the shield until it is exactly
opposite(and equal) to the outside charge. The intenal charge has to
move because it is out of phase with respect to the external charge
thus it is forced to accelerate or decellerate if you will to its new
position or resting place. While this internal charge is moving the
flux that it is carrying is transformed into a time varying current
such that the charge is now without energy and static and its energy
in the form of a time varying current has moved on outside of the so
called boundary in the same way it in initially entered our boundary.
Thus at this point we have located the where abouts of all energies
involved by adding all the "instances" of time (dy/dx) until the
instances added up to a period of time for the frequency applied.
At all times where the energies are at rest there is no accelleration
and the energies dissapate into another form or state.
As you can see David I have concentrated on energy asd opposed to its
form where we applied an energy at the transmitter where it was
reciprocated at the receiver. Mention of waves or particles have been
deliberatly avoided and we have accounted for all forces or energies
involved for a cycle.
Now we do not have to let it rest there.We have Maxwells equations for
radiation and with todays computors that same equation can be oriented
such that if you input a radiator it will change the input to the

metrics of Maxwells equations which is a wavelength to satisfy equilibrium. Thus the program only accepts input metrics that are included in Maxwells equations such that equilibrium is adhered to at all times
When applying a radiator to such a computer program it will supply a accountability of all forces that follows the intents of Maxwell.
Thus when the program has done its stuff it will supply a full accountability in terms of 100 percent,
Thus I have supplied a sequence of "observables" that relate to the experimental results of Faraday. I then applied the same situation to the accepted Maxwell mathematical equations which also provided 100% accountability.
Both of these approaches result as equals. To satisfy those who have positions of duallity I have used energy terms alone without the description of its carriers.
So David, I have provided all for your dissemination, where you can break it up into scientific parts for comment including desired additions required to fortify a position. It is rather long and detailed but in no way can it be seen as "hand waving". At least you seem to be alone in sticking to physics without being dominated by emotions.
One can easily hang a piece of mesh and connect it both to the ground and a radio and both charges will take a separate path since they are divided by a conductor into two separate entities.
Best regards
Art

My ECA book gives: Si-N, 35V, 0.5A, 50MHz and suggests; BC817, BCX19,
2SC3325 or 2SC3341.

p.s. talking energy when trying to figure out what happens with waves is counterproductive. energy is an integration of power, power is a function of current or voltage and impedance, or field strength and impedance of the medium... when you go from fields or current/voltage to power you lose phase information that is important. integrating it into energy loses even the phase and time information. it is always best to describe waves by using one field or the other, which one is up to the student since they are always related by the impedance of the medium... the same goes for currents or voltages on conductors, pick one and stick with it, you can always calculate the other when needed.

There is a neat shortcut. :) Someone told it to me after I'd been wading through Google and all the parts brokers nonsense out there.
http://www.findchips.com
The name sounds like any other inane parts broker with no actual inventory, but go there, you'll see it isn't. Once you see a part offered by a couple of sellers you can likely get a data sheet that is up to date, and further, Digikey and Mouser have search tools good enough that you have a fair chance of rading a data sheet for parameters, entering a few into those search tools, and hitting a few good substitutes.

You stated that nobody knows how waves work so I took energy
contained as the route. I can't explain how waves work either and I
don't want to start of with an explanation how a wave works.
So the impasse appears to me that first I have to explain how waves
work instead of mass but also to continue on with the same theory and
then apply it to another theory! It was stated earlier that a mouse
trap can kill a mouse with less than 100% energy, so you require an
autopsy to show how and why and if it is really dead! You can do the
same by connecting a radio up to a mesh. You find how it can transmit
and receive such that it is NOT dead, that is the easy way.
We are now back to the prosecutor declaring one is an idiot where the
judge retorts, as another example of free speech, that the prosequtor
is a homosexual, but now requests the prosequtor to present evidence
proof or you will be arrested!
I am not guilty as I have presented a paper for my peers to agree or
disagree on the basis of science. Unfortunately my peers in science
have not yet arrived. Either way, thanks a bunch for your efforts and
sticking to physics and not free speech.
Best Regards
Art

O.K look at things another way where the given theory interlocks with
even more branches of accepted science.

When you apply Maxwells equations to an array it can only supply
radiation from forces that are supplied. If all is not supplied ie the
array is not in equilibrium then it accounts for only what is
applicable.
A yagi is not in equilibrium so Maxwell can only supply radiation
evident by other laws or another arrangement that the programmer has
provided, which will be in the order of something less than 100%
If the result is 100% accountability translated into 100% efficiency
then the array provided conformed to a Maxwell arrangement in
equilibrium
OR the programmer provided methods for the program to reorganised the
array to conform with Maxwells equations which requires equilibrium.
Thus Maxwell declares the difference between equilibrium
and non equilibrium. The final test in terms of physics and astromoney
and the laws of Newton is that the vectors of radiation must be equal
to opposing vectors such that equilibrium is retained. Maxwell does
this by supplying two vectors for radiation which is balanced by
gravity and the rotation of the Earth which are accepted external
influencies
with reference to the Solar system. These same two vectors are
reflected thru a series of interchanges per Newtons law where it
inevitably it finishes up with the big bang where equilibrium is
broken by the introduction of the same two vectors, one straight and
one with spin content which is axial or otherwise ala, helical in
content.
It is the same two vectors which all the Universe is compared to as a
datum level that portrays the difference between equilibrium and the
breakage of equilibrium. This can be stated because without breakage
or change from equilibrium movement cannot occur and the solar system
cannot exist. This was visualised by Einstein with out the success of
deducing the initial vectors such that he turned to the science of
Relativity in the hope they would then be exposed before he went to
his death.

Another aproach to radiation
Using a common dipole we have two variables,length and cross sectional
area.
Mathematically we can reduce length to a minimum thickness where by
the crosd sectional area must increase a given amount to retain
equilibrium. This clearly shows that the provider or receiver of
communication can be in the form of a flat plate conductor or same
that is perforated.
Remember that at no time have I invoked Gausss field when made dynamic
which both you and I agree to and others do not. Which forces
interlocking of physics proof from other accepted physical facts.
proof of interlocking as I have supplied.

Yes, I agree we are at the end, with you only agreeing with the
admissability of making the Gaussian field dynamic which equates
mathematically to Maxwell. At least that shows a progression from the
particle domain. With hands being tied with respect to that approach
and the other approaches offered are not accepted by you for
unspecified reasons. Hey, we gave it a shot with respect to physics
and did not have to substitute insults under the umbrella of free
speech If you hear me on the air I will be using the prescribed
radiator
and if we do not make contact then you can rest more easily with your
own thinking. I had hoped that the transition from ham radio to CB had
not already occured in the hope that some of the original amateurs
were still alive who were well versed in antennas and physics but we
are now in another eara. Both Europe and Japan were showing big
signals yesterday so things are looking up.

> needed.

You stated that nobody knows how waves work so I took energy
contained as the route. I can't explain how waves work either and I
don't want to start of with an explanation how a wave works.
So the impasse appears to me that first I have to explain how waves
work instead of mass but also to continue on with the same theory and
then apply it to another theory! It was stated earlier that a mouse
trap can kill a mouse with less than 100% energy, so you require an
autopsy to show how and why and if it is really dead! You can do the
same by connecting a radio up to a mesh. You find how it can transmit
and receive such that it is NOT dead, that is the easy way.
We are now back to the prosecutor declaring one is an idiot where the
judge retorts, as another example of free speech, that the prosequtor
is a homosexual, but now requests the prosequtor to present evidence
proof or you will be arrested!
I am not guilty as I have presented a paper for my peers to agree or
disagree on the basis of science. Unfortunately my peers in science
have not yet arrived. Either way, thanks a bunch for your efforts and
sticking to physics and not free speech.
Best Regards
Art

Actually Art, I said that a mouse trap can kill a mouse with less than 100% efficiency. It may not catch all the mice, but the mice it catches are all dead.

Schroedinger is the guy who had a half dead, half alive cat in a sealed box, but that's an entirely different kettle of fish!

:-)

i have been very specific about why they are not acceptable, there are
no specific equations that relate to something measurable, nor have
you made any predictions of things that aren't already well described
by existing laws and theories.

Another aproach to radiation
Using a common dipole we have two variables,length and cross sectional
area.
Mathematically we can reduce length to a minimum thickness where by
the crosd sectional area must increase a given amount to retain
equilibrium. This clearly shows that the provider or receiver of
communication can be in the form of a flat plate conductor or same
that is perforated.
Remember that at no time have I invoked Gausss field when made dynamic
which both you and I agree to and others do not. Which forces
interlocking of physics proof from other accepted physical facts.
proof of interlocking as I have supplied.
Art

Hi Art,

If I read this correctly you are saying that as a dipole antenna is reduced in length relative to a given frequency, it must be increased in thickness until a point is reached where you are left with two closely spaced parallel plates which are the equivalent of the dipole.

The plates need not be solid, so a perforated or mesh surface will do. You have mentioned how to form mesh structures a few times, so I assume that this is what you are using.

Fat dipoles are inherently broadband, so such an antenna will be compact, efficient, broadband and cheap if constructed from mesh.

Sounds like a reasonable experiment, but I don't think it needs any new maths to describe how it works. The existing theories already back you up.

Cheers

Well actually I was infering that for minimum thicness of the plate
",area" must be increased. However if I had thought a bit more ,your
explanation of two close spaced plates is a better description since
there are two entities there as with a water chamber separated by a
flexible gasket. Thus we have an application where a water analogy can
be used for energy transfer ie. Volume can change from one side to the
other by the deflection of the membrane yet the two entities still
stay separate. Neat.

Yes that sums it up.

>
> Fat dipoles are inherently broadband, so such an antenna will be compact,

Yes,I was illustrating the use of mathematics to show that two
entities were actually the same because mathematics appeared to be the
choice of proof. Nothing more.

>
> Sounds like a reasonable experiment, but I don't think it needs any new

I fully understand that, but when the group denied existing physics in
favor of requesting a different proof perhaps a new technology then I
was lost for words. So when DR Davis of MIT came along and confirmed
what I stated the group attacked him also. We never got beyond the
point of legality of adding a time varient to Gauss's law such that
Maxwells equations could be applied. Unfortunately this also presented
the presence of particles albiet static particles so interpretations
of the double split experiment got expanded beyond the spectrum of
light of which there is no proof. Thus an opening for
insults without explanation required A boon to those uneducated in the
field

Something of a contradiction in that statement.

Rhetoric aside, what these threads have absent are science and
engineering (usual problem of the CBer's fantasy, or "How I patented
Perpetual Motion"). If you are going to make such a statement as
found above, then how fat does a dipole have to be, to be compact?

Let's make that simpler. Take a half-wave antenna as the benchmark,
at its natural first resonance. How fat does it have to be for us to
be able to cut its length in half and still operate at that same
frequency? In quarter? In an eighth?

Let's get a little more complex (but is actually the same question as
above). Take a half-wave antenna as a benchmark, at its natural first
resonance with a #12 wire. What multiplication factor is necessarily
applied to that #12 wire thickness to make its length half at the same
resonance frequency? What multiplication factor for quarter? For an
eighth?

Extra credit question: How much does volume of the structure vary
against fattening?

****
Reductio ad absurdum
****

The notion that the fatness of the wire expands as the wire length
contracts leads us to two parallel plates separated by the distance of
the insulation of the coax inner conductor to shield. This is called
a capacitor. At any practical RF frequency, a substantial capacitor
is a short circuit placed across that transmission line. There are
easier ways to short a transmission line that are even more compact -
I will leave that to the student to derive.

Consider the current in that capacitor's plates which would run radial
from the feed to their edges. When the former dipole was radiating,
those currents were in-phase and they contributed to radiation. In
this novel degenerate design, they both have moved to the opposite
polarization and are anti-phase where their fields cancel.

So, this degenerate dipole is designed to short out, and to cancel all
radiation (same thing as a shorted transmission line without any

antenna connected).

****
The proper fat dipole
****

Described by Schelkunoff (student of the Univ of Wa here in Seattle) as two cones driven at their apex that meet at the feedpoint. The half design is the Discone. Anyone who has used or designed such a fat dipole can attest that it is the same slant size as a dipole is long (meaning that the overall length is shorter but that the significant dimension is not) and as for fatness, this could be a multiplier of 10s of thousands.

> by existing laws and theories.

David, the acceptance that equilibrium must prevail for toatal accountability states that one cannot use a 1/2 wave radiator as a basis for the application of Maxwells equations. Why is this? Because equilibrium is determined by a period. If each half wave that constituted a period then one is saying that the half wave resonant point is half way between the beginning and the end of a cycle. There is a resonant point but that same point is NOT repeatable thus one must refer to the "period point" for equilibrium.
Physics does not squable with this assertion,amature radio does by ignoring equilibrium requirement.
Moving on with this revealment we can then say that a radiator can be any shape ,size or elevation as long as it is in equilibrium when Maxwell can be applied for accountability for all forces.
Thus a radiator can be deformed ,reshaped or condensed and still be applicable to Maxwells laws as long as equilibrium is held to.
Imediately we can therefore deduce that lumped loads if provided must be cancelled to retain equilibrium. Thus the application of equilibrium as required in physics provide a path for the design of compact radiators where all forces are accounted for as well as maximum radiation.
To ask for mathematical proof of the requirement of equilibrium or balance which is the root or datum line for all physics is patently absurd and immediatly declares all prior physics laws supplied by the masters as void and redundant as all are based on equilibrium.
The real problem here is that when Maxwell by the use of mathematical rules with his equations showed that mathematics easily supplanted past investigation by observation that all physicsts were lead to believe that mathematics over rule observation. Thus we now may use mathematical deductions such as probability to substitute for observation knowing full well that a punter at the race course will lose all by continuous betting on favorites and it doesn't happen that way in real life. If my memory is correct "probability" was the path taken in the double slit experiment in the face of tha absence of a

true mathematical or observed factor . Since the results matched consensus among physicists the subject was considered "solved" never to be questioned again. And worse, expanded beyond the limits applied in the test. Imaginary answers provided! Don't worry, since mathematics rules all so imaginary can be seen as factual. Same goes for Newtons laws where he stated that every action has an equal and opposite reaction where present day students now add "diametrically" to further describe "opposite" which is not the intent of Newton initial determination. Now we have CERN spending billions on accellerating particles instead of the prior determined waves. O my!
Art

I can well imagine that the bright inventor, the holder of innumerable
patents validating a new physics, could counter this problem of
anti-phase cancellation.

The two currents are adjacent because of their feed point design.
"Change the feedpoint design! (Remarkable insight solves the
problem.)"

How?

"Move the feedline every so slightly away (so slight that not even
Richard could complain)."

Richard doesn't complain ;-)

"Now, take a wire and connect it to the extreme edge of one plate and
connect it to one of the two feed wires. Then take a second wire, and
connect it to the extreme, BUT OPPOSITE, edge of the second plate."

Richard mildly points out that this solves the problem out to the
edges of each plate and restores radiation, but then the current turns
back towards the feedpoint along either plate that is a massive short
and cancels the new wire out. :-O

The cracker-jack holder of patents then would retort: "Remove the
plates and that problem is gone!"

.... and we are back to the conventional dipole which proves this 2nd
order degenerate design IS more compact.

****** tear on dotted line and return ****************

Have we gotten any practical contra-example to the simple dipole being
100% efficient? You know, a real design that describes frequency,
length, and width of wire? [I realize this may be a tough obstacle to
surmount. Dimensions are sometimes novel concepts in these threads
that challenge the most cerebral of patent holders. In fact, I can
accurate forecast without aid of modeling that any response from Art
to this posting will focus on parenthetical comments rather than

science.]

Richard

I have a personal preference for discone and log periodic antennae for the wide frequency coverage. Which is kind of why I suggested the interpretation of Art's design that I did. It is difficult to picture some of his designs from the descriptions at times.

As far as 'compact' is concerned, I guess I would suggest an all band HF antenna that could be contained within a 2 metre cube. That's just a personal interpretation with no justification whatsoever and I know that a lightbulb wired on the end of a bit of coax fits the bill.

Your points are well made although some of the first transmitting and receiving antennae were parallel plates coupled across a spark gap. From photographs I have seen, they look to be resonant somewhere in the current VHF band, not that it was of any consequence as the experiments were only conducted across about 8 feet. Could have just been magnetic induction coupling from the transmitting and receiving coils... Now there's an idea for a novel antenna.

One thing you need to understand is that Art has no designs. Even his patent applications contain the written and drawn versions of bafflegab. He has never designed, never built, and never tested anything that performs like his claims. All he does is pontificate. And he ain't the pontiff.

The Hitachi data sheet doesn't indicate anything really special about
this part. It's a standard 35V part with 500mA continuous current
rating. The SC59 package can usually be substituted by a BC817's SOT23
size, with carefull soldering to cover the (possibly) longer pad
pattern.

Hi Mike,

Quite true as to band and dimensions. However, those are balanced
(dare I say in equilibrium?) in comparison to all capacitor and no
inductance with currents bucking each other.

That's what I was thinking too, but the low gate capacitance suggests good for RF, and the first post came from rec.radio.amateur.antenna, so I didn't suggest spreading the search beam too wide because I don't know enough about it.. But the Towers book didn't suggest that high in RF either, nor does the data Ian Fields posted.

Hi,
This transistor goes to generator - quote " and the following 2SC2618
NPN transistor operate as a current source for the AD9851 DAC bias
circuit."
So what you guys think, something like bcx19 should be ok?

Beyond me to be certain, but it looks like 'yes'. That doesn't sound like it's an RF or otherwise demanding task. Don't pick something with poor noise specs though.

He head not empty. The truth in he claim is quite obvious for all
to see. If old man Unwin had an antenna that actually performed
with even half the gusto of his claims, he would not have to resort
to pseudo science mumbo gumbo in order to try to convince people
that he has.
In fact, he wouldn't really have to explain a thing. He could just
mount it on a pike and let it do the talking.
But it's hard to claim radiation efficiency of 100% when you
are using a contra wound dummy load. He might beat out
Mike's light bulb dummy load, but by only a slim margin.
My calculations show that any minor increase over the
efficiency of a coax fed light bulb are not sufficient to cause
the delusions of grandeur which seem to possess Unwin.

So what say Jaroslav, o man o vision.. Can *you* prove that Art
has designed, built and tested any miracle whip that performs
as he claims?
Hold my breath not, sayeth Yoda.. Chortle..

Well, no response as far as I can tell which means that Art cannot
produce a simple description of wire gauge, wire length, and wire
excited frequency (admittedly a pretty difficult demand to place upon
a guru) for an antenna that is in equilibrium and displays efficiency
better than the 100% which is commonly available from a simple dipole.

From the Laotse Tao te king:
"More words count less."

Hmm, on the subject of Chinese kings...
"A king was pleased with the help of a warrior, and asked what the warrior would take as reward. The warrior said, a grain of rice on the first square of a chessboard, on one day, two on a second square, and the second day, until the board was used up. The story goes that with every doubling to 64 squares, the warrior bankrupted the king within two months."

But I ask: how much rice CAN you fit on a chessboard?

I wonder if Art might recognise that little homily, and my question, as a parallel to the effect that an antenna need not pointlessly strive for 100% efficiency, but instead to get a practical and useful propagation or low-noise collection. If you really want a tiny antenna, never mind inefficiency, catch what you can and use it. Ok, too many words from me.

As Paul Harvey would say "and now for the rest of the story"

The inventor asked for this reward as you described and when the
Prince discovered the cost, the Prince (using your analogy) mismatched
the inventor's head from his body.

No doubt something all inventors should consider as the price at some
level....

Funny, nice use of 'mismatched'. I don't think I'm much of an inventor, the couple of things I came up with were small (zero-crossing switch, and analog modulated laser diode driver, laser power meter gain stage and scale/offset tweaker), built partly by trial and error, but they all worked reliably when I'd otherwise have needed bigger, more elaborate and more expensive answers made by other people. But likely have probably nothing to offer than can't be had better elsewhere. What they did do for me, generally, was firmly establish cost as an engineering unit. One day we might even measure it with an SI unit. ^O

Well, I have to be honest and say that I haven't truly finished it. :) It's based on an LM317. I have this LM317 fetish based on admiration for the old POW radio ideas, I really think it's cool that such a ubiquitous device can be applied so perversely to such amazing unintended uses, and given its chances of being found, designs based on it could be buuilt even if much of civilisation were 'bombed back to the stone age'. On a more prosaic level, it's dirt cheap, powerful, easy to build with, and contains useful features.

The driver worked in my initial test to 50 KHz, better than the 10K most analog mod drivers seem to favour. I tested it with a square wave and the edges were sharp with no overshoot if I didn't push it too hard, and did some filtering with low ESR tantalums for supply decoupling. I later discovered LTspice. :) I modelled it with that and quickly saw the same waveshapes my 100 MHz scope had shown me, which was a nice reality check that proved that LTspice could likely similaute the design and let me improve it before rebuilding. I devised a circuit that cannot be overdriven, attempts to do so merely broaden the peak at max amplitude, it cannot overshoot, and will modulate to 200 KHz. The proof is in the pudding but the truth is I never got round to baking the pudding. Bought a slower version of the op-amp I needed but got mightily disillusioned about the laser show thing and felt that I'd either build it and gain nothing personally from it, or no-one would even care. Given what I'd seen, I think this is genuinely true, few would. I hadn't even decided if I was going for SMT or through hole, and it's a tough call because available parts seem to force a hybrid... Like the pitch-to-MIDI system I wanted to build as an adapted version of Doepfer's R2M control system, it got put on the back burner. But I spent a couple of years pulling together all the tooling and design files to do it, and when I find something to motivate me, I intend to finish both these projects.

I think this is what's drawing me to SWL. The present stopped compelling me, so in a way I'm drawing on something that endured from further past, as a way

to revive the spark that got me as far as I did get. I never found a way to gauge what I do, because most times I find little to suggest that what I do has anything that people can't find better elsewhere just by throwing money at it, and as they usually have more than me I tend to think they're probably right. But if I can find enough motivation just to do it even though it might amount to nothing, I will do it because I don't know what else I'm good for.

Long spiel, but I think I needed to, as part of whatever I have to do to make it happen. Like Mulder, I want to beleive, I guess..

I have never said that, not even once. So how could I be fond of saying it?

And Art has also not once posted a single measurement, a single equation
or a single design.

And you have never done anything but snipe.

Yes, so do I, but I also occasionally make contributions, and my claims
have always had numbers and measurements behind them.

Do you know what measurements are?

Actually, given my previous post, anyone familiar with all that is mentioned in it can deduce how to build the diode driver and probably get lucky choosing the op-amp. I want to keep it under the hat I haven't got for now, but if someone comes up with it independently, go for it, I just hope it gets shared and not patented. People say no way 200 KHz analog proportional mod out of an LM317 as diode driver, but I'm fairly certain it's viable. LTspice certainly thinks so, and its output matches what I've seen of real output so I think I believe it. Not an antenna thing, so I'll leave it there. Nice to be able to talk of it though. Keeps it alive somehow.

200. Dissimilar metals at antenna Mount

I have a collinear J pole that I made out of copper pipe. It is
mounted on a galvanized iron coupling at the top of a piece of
galvanized iron pipe. I want keep all parts of the mount at ground
for lightning protection while avoiding corrosion between the two
types of piping. If I use a dielectric union to connect to the
galvanized iron mounting but I still bond both the support pipe and
the antenna base to ground can I avoid the galvanic action that
already caused the two pipe threads to gall.

Hi Tom,

Galvanic action occurs at the interface of two dissimilar metals with an electrolyte between them. Each metal/electrolyte combination constitutes a "half cell" with a potential characteristic to that metal. When combined, they form a total potential which supports current flow and metal migration. You can build a chain of such reactions through intermediate steps (a chain of connections); but the current flow still is a product of the electrolyte between them (the half cell chemistry) and if you can break the chain, you break the current and the metal migration.

The chemistry is not complex, and it occurs in nature without too much difficulty - hence the problem with weather and poor sealing. A saltwater environment is classically the most brutal. Toss in acid rain too. The solution is fairly simple, but the success of implementation, as the devil, is in details. One simple problem is you may seal the joint or connection from the outside elements, but you may also be sealing the contaminant in with the joint or connection. Now you may observe that two solutions are required. There are a variety of products that can be used to flood the joints to reduce/prevent both these problems. Others will chime in with commercial names and their experience.

As there is potential developed, and a current flow, you could in theory detect a bad coupling. Oddly enough, the two metal combination could by absolutely dry, free of contaminants, and still give a voltage indication. This would occur on the basis of a temperature driven migration of current (the Seebeck effect) and you have what is called a thermocouple. This, however, is a very small potential in comparison but could still surprise the investigator. Here, the effect is not chemical but is a heat characteristic of each metal (which means the two metals combine to create the perceived voltage through their individual contributions just as in the galvanic cell). Given that most metal joints in a circuit occupy the same temperature environment there is no potential difference developed.

Most technicians consider these potentials as inconsequential (barring the corrosion), but when it comes time to make accurate measurements of small potentials, they can become galling to the patience.

One consequence of these interfaces becoming contaminated is that you can also develop a non-linear conductor or a primitive rectifier. If this is a path for RF currents (a common mode from your transmitter) you can generate or receive spurious frequencies. Oh happy day.

Would sacrificial action be appliable? Magnesium blocks are sometimes used to prevent chemical action taking place on less reactive metals electrically connected to them. I'm not sure if it can be applied though, that trick is usually done with grounded (usually buried) blocks to protect pipelines, etc.

I transitioned from galvanized to brass to copper by putting a brass
union between the antenna and mast.

Havent had any problems. I also use anti-sieze.

Well, I doubt if this could be put to use for Tom. Some of the
sacraficial methods actually use a reverse bias to combat not only the
anodic reaction, but currents that occur naturally or flow between
service grounds.

maxwell's equations know nothing of the length of a conductor used as
a radiator. in fact, they say nothing about a conductor at all.
where in the equations is there even a length specified?? in the
differential form everything is reduced to either a gradient or curl,
there can of course be no length since everything is reduced to an
instant in time or a single point in space. in the integral form they
are done over volumes, over surfaces, or around closed loops, all with
arbitrary boundaries. And in none of them is there a conductivity or
resistivity term applied that would be necessary to model a conductive
element.

you might also be interested in this paragraph from Ramo, Whinnery,
and Van Duzer's "Fields and Waves in Communicaiton Electronics" pg 237
section 4.07 that puts your insistence on adding a 't' to Gauss's law
in perspective:

"Equation (1) is seen to be the familiar form off Gauss's law utilized
so much in chapter 2. Now that we are concerned with fields which are
a function of time, the interpretation is that the electric flux
flowing out of any closed surface AT A GIVEN INSTANT is equal to the
charge enclosed by that surface AT THAT INSTANT."

Emphasis is THEIRS not mine, they were obviously anticipating your
objection and explaining why it isn't necessary to add a 't' to the
equation. I would put the 3 of them against your dr friend any day of
the week.

Does Maxwell even use the word resonance? Reactance? Or any word
from the host of electrical components? Maxwell never even used the
term Gauss to signify the strength of a field! And neither did Gauss.

What DID Maxwell say about equilibrium?
"About the beginning of this century, the properties of bodies
were investigated by several distinguished French mathematicians
on the hypothesis that they are systems of molecules in
equilibrium. The somewhat unsatisfactory nature of the results of
these investigations produced, especially in this country, a
reaction in favour of the opposite method of treating bodies as if
they were, so far at least as our experiments are concerned, truly
continuous."

Richard

If I use a dielectric union for the joint and bond around it for
lightning safety will that solve the corrosion problem by preventing
direct contact between the two dissimilar metals or would the bonding
cause the same destructive current flow as the direct contact?

Hi Tom,

I don't know what you mean by bond that is both insulative to cathodic action, and conductive to lightning. To me, bonded metals don't introduce a complaint of anticipated galling. If they are bonded (soldered, brazed, or welded), you don't expect to disconnect them and suffer galling problems. If they are soldered, brazed, or welded, then the seam can still support cathodic action - it is simply a cell loaded with the short of the bond if I read it that way.

I don't often find myself in your situation, so I have little to go on beyond the common discussion. I have had to deal with these issues with fine measurement where it is always lingering and it often took heroic effort (careful, this is hyperbole unless you have to make a living at it) to succeed.

Jimmie may have something more to offer.

All I know is I haven't had a problem with corrosion. Apparently the brass is is similar enough to both copper and the galvanized steel or maybe the rain here is not so corrosive, maybe its the anti-seize. I actually cant say with certainty that if I connected the copper directly to the galvanized pipe I would have had problems. Somewhere I learned, possibly wrongly, you should join copper to galvanized plumbing with brass.

Has anybody noticed? This appears to be a pointless exercise.

How can you explain such concepts to one who has no understanding

of elementary math.

73,

Frank

Jimmie & Richard
Sorry for not being more clear. I was asking if the use of a
dielectric union to join the two pipes would prevent the corrosion of
the threads of the union now used instead of a galvanized coupling
even if I still had lightning down conductors connected to the bottom
of both pieces of pipe. In other words the two pieces of pipe would
still be joined mechanically by a dielectric union and electrically by
the lightning down conductor. What would be different is that the
electrical connection would no longer be occurring at a point of
contact between dissimilar metals which would be separated from each
other by the non conductive washer of the dielectric union.

Hi Tom,

I would offer that this non-conductive washer will not solve what you
perceive to be a problem IF it has any water (solution) that can
bridge it.

>I still had lightning down conductors connected to the bottom
>of both pieces of pipe.
This specific information guarantees a current path for the galvanic
action, IF water wets both sides of the insulated washer and joins
them.

Instead of washers (this is all pretty vague in the geometry), you
should go for insulated stand-offs to increase the separation so as to
allow water to wash off rather than to bead up and join the two
metals. An oversize (as in very wide) washer might do.

Hose down the join and look at the water's wetting of the join.

That's true, but it also suggests that sacrificial action can be worked. If water with ionic contaminants bridges the gap (across the dielectric) to close a local circuit, cause current flow and corrosion, then it's a loop that presumably does not place current in a signal line, or any resulting noise (but considering that a galvanic battery is not generally noisy, that's probably irrelevant). Jimmie mentions interposing brass between copper and galvanised (zinc coated) plumbing, and surely that would be to reduce potential between dissimilar metals and so reduce current and corrosion at each junction, but ultimately one metal will gain metal from the other in the join, (usually as a mess of salts), but so long as the one that loses is the negative electrode in the loop, and is a sacrificeable part, then until it needs replacing, the only other maintenance needed might be a wire-brushing and regreasing. Short of ensuring same-metal interfaces, I can't think of another strategy except to seal out moisture, and ideally gas too.

I have this problem - my garden is not too large (about 15 X 7
meters).
I wonder, between the diamond WD 330S - is about 10m, and BB6W - 6.4m.
Or maybe some vertical?
Can you advise something?

Boris

Well, yes.
Of course, I mean work on short-wave, and it would be good to have the
80-meter, which is probably possible with these antennas.

I just bought a vertical whip mast that comes in nine one-metre tapered sections. Very light and easy to use. It looks like it will also be easy to omit upper sections for a shorter and more rigid whip. Listing 290381933076 on eBay shows one. Designed in Italy, made in China, so likely widely available.

Right now I have scaffolding works going on outside, landlords doing their ten-yearly maintenance, but I might still get a chance to set this up soon because it's a very undemanding antenna design. I'm not sure how well it will stand if I try for permanence but I think it will be fine if it doesn't get a direct hit, and it's too light to damage much it it does.

Hi Boris,

You can listen to SW and 80M with almost any kind of antenna and a
cheap tuner.

Save your money.

Hi Boris,

You don't need to spend $300 on an antenna to transmit on 80M when $10
will easily do this. Are you licensed to transmit? Do you have a
call sign?

The problem here is that you came to the group with a specific,
expensive solution (or two actually) and a rather unspecific problem.
If you are looking for validation for these expensive antennas: yeah,
sure, buy them both and work in stereo.

If you don't have plans outside of 80M and listening to SW (you
haven't provided anything more specific than this, and even then I am
guessing); then a short, custom tuned 80M antenna is easily achieved
for chump change - and it will work quite fine for SW.

If you have more grandiose plans (undisclosed so far), then sweep the
table clean and start over again.

Ok, so from the beginning.
I have: a license, radio, and at that moment just listening on a piece
of wire ....
I am thinking about those two antennas due to some small garden
(only home and a piece of garden flat - no trees),
and partly because my experience shows that sometimes it is better to
spend some money right away to something decent, than to buy some
bullshit.
But that's what I wrote, it's not gospel - just ask for advice from
more experienced colleagues.
I am open to everything, and if it is cheaper than what I ask is just
better.
I must admit that I do not have much experience in this field, and I
do not know how it looks in practice, but I would like to work on all
short-wave.
If this is rubbish, please tell me which ranges should be considered

Boris

Hi Boris,

Not knowing what bands you want to operate, how much loss you are
willing to accept, how much money vs. how much of your own effort you
are willing to spend; this all makes recommendations kind of tough.

If you are only working 80M, then a simple antenna will do - but I
don't have enough information to say skip the expensive solutions.

However, I would say spend your money on a tuner and put up a dipole
that fits - or a vertical that fits. Don't worry about anything else
until you have something to fix, you could spend a lot of time
worrying without getting anything done.

This is a link to an article on how to move a mast down the road legally. It's about getting the mast or tower up and over the vehicle and then now to make the trailer pivot differently than the tow vehicle.

I thought it just might transfer over to moving towers and such.

The link is-
http://www.tongacharter.com/report-mast.htm

And... dang, no way to post a photo. That was the point. Well no worries, the article has the photos, but it's more fun to post them here.

Boris,

I made the T2FD antenna myself (look-alike of the WD 330S)
Very quiet antenna and very easy and cheap to make (1 balun 1:1 and 1
resistor, some pvc-pipes and wire)
I believe you're Dutch (or Belgian), so if you give me your callsign or
e-mail-adress I'll sent you some info.
But remember, a T2FD is not the most effective antenna, acts more as a huge
dummy-load ...

Scott,
Reminds me many years ago, when I lived in a small farming town, our family company built a 100 foot self supporting tower some 3 miles away from where it was to be erected.
The tower was constructed in one piece and to get it to the site we simply used a small 6x4 ft box trailer under the large end on a turntable made up out of two lengths of 8x4 inch pieces of local hardwood (actually railway sleepers) and that assembly was fixed to the box trailer. The trailer was fixed to the tower with the tow hitch facing backwards.

Up the front we slid a piece of 2 inch pipe in the antenna mounting spigot and attached a small tractor to tow it to the site. The reason behind the turntable down the back of the tower was that we had to deal with a narrow timber bridge with a right hand turn at the end of it, and just 200 feet further on a Tee junction and just after that a final right hand turn of some 120 degrees. When we needed to turn the large end to manoeuvre it around the turns we simply pulled out the lock pins on the "turntable" and rotated the box trailer and manoeuvred the large end of the tower around each turn.

In those days, the 1960's we simply rang the Police and they came out and stopped the traffic for us and we accomplished the move in about 20 minutes. Today it would be impossible to achieve that because of the red tape.

The tower is still standing now and supports a heap of mobile phone antennas.

Ahh for the good ole days!
John in Australia

As I sit here not participating in the Jan VHF QSO party partially due
to a cold but mostly due to freezing rain, I wonder. I wonder what
stories and advice the group has about this sort of situation on VHF and up.

What sorts of design and fabrication details work to make antennas
perform well in environmental extremes?

Several years ago the only thing I had working until after the thaw
was a 20m square loop.

Agree....
No way to participate this year.
Have so much ice hanging I dare not move anything.
Lost the 40 and 80 meter inverted vee set up yesterday.
All three towers and the ground mount 160 vert are intact, so far.
Wind is howling, power is on again off again.
Hoping for the best at this point.
Northeast Montana is not a nice place to be right now.

Up here in Alaska we use covered Rotators, Bearing Shields, Low Temp
Freezer Grease, and heated Radomes to keep things working clear down in
the -60F range. Freezing Rain means you just have to keep the rotator
moving back and forth, every few minutes, to keep the Ice from building
up on the rotary sections....

The statement 'while old-style TV transmissions could generate one
million watts, digital transmissions are much weaker' is nonsense.
The coverage of the digital services in the UK is matched to that of
the analogue services and, if we can receive the signals ...

That was the mistake IMHO of Contact. Although it would have made bad movie action, there were many years of morse code and audio long before "Uncle Adolf's I'm the Master Race and You're Not Show" was supposedly broadcast.

Not counting the fact that the Germans did not broadcast it, television in Germany at the time was shown in special theaters and AFAIK delivered by telephone lines (anyone who knows differently feel free to correct me).

Long before Howdy Doody and McCarthy were two world wars and so on.

What I think would be more likely their question if they landed is "What happened to the people who were going to go to the stars?"

While we may have faked the moon landings or not, 40 years later the only way we can tell is to look up at the sky and hope we can see something.

A manned moon landing now is just science (or historical) fiction. :-(

Geoff.

Especially if they had to watch Howdy Doody on a 7 inch Hallicrafters black and white rack mount TV screen. Which is where I first saw it on WICU-TV in Erie, Pennsylvania.

Or the first TV received broadcast ever seen in College Station, Texas, on the top floor of the Bolton Hall Electrical Engineering building at Texas A&M College here in I think 1946 on Parent's Day that year. That was on Channel 2 from KPRC-TV in Houston that prized day. On a flying spot scanner which I watched. I asked, "Why up on the top floor of the building?" Answer, "Mike, how else do you think we can afford an antenna up high enough to see the TV station signal from Houston?"

Hmmmmmmmmm.... or Whirrrrrrrr.. depending on whatever, grin...

Any sufficiently advanced communication technology is
indistinguishable from random noise.
--Richard Factor's Corrolary to Clarke's Third Law.

This may explain why SETI is having problems finding alien
transmissions. If they're using UWB (ultra wide band) spread spectrum
from DC to light, then it's unlikely a narrow band coherent detection
system is going to find their signal.

I'm thinking of what we did in the Navy: Encapsulation of one sort or another. Radomes got mentioned already so I'll add rubber boots over connectors and a generous coating of Scotchkote (or equal) over exposed hardware.

Military antennas are usually over-built, as are the mounts. They WILL stay together in one piece and they WILL stay up or somebody's going to hear about it! For hams in vicious-weather zones, maybe it means using plumbing pipe masts instead of thin-wall galvanized tubing. Maybe it means more guy wires. Maybe it means paying ten times extra to buy the absolute toughest item you can find. Maybe it means buying something tough -- something made for a nearby commercial band -- and laboriously modifying it to work at 2m, 220 or 440.

Without intending to demean any single approach, you may be facing a tradeoff: Do you need to build a $2000 indestructible antenna setup or can you replace a $300 one a few times? When the welfare of 6000 men on a billion-dollar ship is involved, the Navy's choice is easy. For us hams, not so easy.

Aside: Wire antennas (not what you asked) usually had a "sacrificial link" in the elements. In case of severe stress due to wind, the link would part, putting some slack in the element but not bringing it down. Until it was repaired, the antenna didn't tune quite like before, but you could still get a match. The link was variously also called the "weak link" or the "breaking link."

Emergency fallback (of which I have several) is the attic antenna. The wet/icy roof attenuates the signals but it's not a blackout.

I wrote something long, then deleted it, but one core idea persists...
Instead of going for rigidity and mass, you could try flexibility and minimal mass, like a reed, feather or twig in principle. I made a 35 foot 'mast' for an FM reception 1/4 wave dipole, from scrap. It lasted 15 years so far, and might go on a lot further yet. It flexes to absorb wind blasts of up to 80 mph at times, or bird impacts, and is guyed (by its own coax plus a couple of lengths of burglar alarm cable) at a 'static' node like that of a plucked string, to minimise stress on guy wires. If any part gets hit, the whole of it takes the strain. It looks like crap but it works and even though we don't get heavy ice it would just crack and fall off it periodically if it got any. Natural motion and flexing would see to that. I got the idea from seeing how well reeds will stand long after winter hits them, and from realising that the dynamics in the aluminium were similar. Its height is several hundreds of times its width, and even if I'd had to scale that up to something much taller, intended to bear more load, I think it might still work better than a rigid tower. But it would be useless for strongly directional antennae. :)

Crucial detail that did not survive the long reply I did not send, or get in
the one I did send: The aluminium was angle-sectioned, and used torsion as
well as bending to absorb force.

The insulated spacer and mount (crudely hacksawed hardwood from an old chair)
for the vertical dipole would damp the oscillations like a kind of 'anchor'
against the wind. The only time anything broke on it was a guy wire when mast
torsion made it bend and fatigue at the attachment point, but the mast never
fell even during the wind that did this to it, and this weakness can be
easily designed out. The metal mast never fatigues because it never flexes
beyond its natural spring tension at any point. If it did, it would have
fallen in weeks instead of lasting many years. The load at the top is only
about a half-pound, but the rest of the mast is less than double that, so
it's very efficient and cheap.

266. RG6 and RG59

Newsgroup: rec.radio.amateur.antenna
Date: 2010-01-30 00:22:50 UTC

Sorry, I strongly suspect this is a very old can of worms I'm exhuming, but here goes...

The web is full of advice (and noise) about RG6 being better than RG59, but a small proportion of experience-based postings suggests that RG59 is often adequate even where UHF signals are used, especially if it includes a foil shield under a braid shield, and it has a foam dielectric. Less common is a point suggesting that for HF (and perhaps CCTV and other video, as well as S/PDIF digital audio) it might be better to use RG59 because its braid is better at screening for these lower frequencies to get better SNR. This seems to make sense, but it is it so? It appears to me that for domestic scales an RG59 with the added foil shield and a foam dielectric might be the best coax to use for low power signals, until some weakness dictates a specific requirement for improvement.

If there was a "best" cable, there would be only one type. Some have lower loss, some are more flexible, some have better weather resistance, some have better shielding, some have a longer lifetime, some tolerate temperature extremes better, some are more uniform, some are less expensive, and so forth.

So deciding which cable is "better" requires a lot more information about what your requirements are.

RG/U specs have long been abandoned by the military, so any manufacturer can -- and do -- use these designations pretty much as they please. One manufacturer's "RG-59/U" or "RG-59/U type" cable can be very different from another's, in many important ways. So you have to look at the specifications of the actual cables you're comparing.

That said, RG-6 is nominally larger in diameter than RG-59, so if everything else is the same, it will have lower loss, be heavier, more expensive, and less flexible.

Multiple shields are seldom important in amateur applications unless you have some seriously strong local signal you need to keep out, or you need to bundle several cables tightly together for a long run. Even then, most amateurs will end up with a lot more signal leakage at other points in the system than they'll get through a good quality single shield.

Speaking of shields, some cheaper cables have relatively poor coverage, so a decent quality shield is sometimes a good investment. Adding foil might make a poor shield better. But I have some popular foil-shielded cable that has bizarre loss characteristics at around 400 MHz which vary all over the map as the cable is flexed. So a poorly designed foil

shield can be worse than a decent braided one.

Foamed dielectric results in slightly lower loss. At UHF and below, this is almost entirely due to the fact that it causes the center conductor to be larger, reducing conductor loss. On the other hand, the velocity factor and impedance vary a lot more from lot to lot than solid dielectric cable, so in length-critical applications you'll need to be able to measure the electrical length of each piece.

That's the five minute coax cable primer. If you dig a bit you'll find out there's a lot more to it than this.

NIST engineers are working with scientists from the University of Arizona (Tucson) and Boeing Research & Technology (Seattle, Wash.) to design antennas incorporating metamaterials – materials engineered with novel, often microscopic, structures to produce unusual properties. The new antennas radiate as much as 95 percent of an input radio signal and yet defy normal design parameters. Standard antennas need to be at least half the size of the signal wavelength to operate efficiently; at 300 MHz, for instance, an antenna would need to be half a meter long. The experimental antennas are as small as one-fiftieth of a wavelength and could shrink further.

Fact or Fiction?

Fiction.

Efficient antennas can be made which are much shorter than a half wavelength. They'll be narrowband and highly reactive, however. What do the scientists say about the bandwidth and feedpoint impedance? Where can we find published data?

Sounds to me like somebody is trying to sell some stock.

Elektor magazine had a news report on these antennas.

"NIST engineers are working with scientists from the University of Arizona (Tucson) and Boeing Research & Technology (Seattle, Wash.) to design antennas incorporating metamaterials — materials engineered with novel, often microscopic, structures to produce unusual properties. The new antennas radiate as much as 95 percent of an input radio signal and yet defy normal design parameters. Standard antennas need to be at least half the size of the signal wavelength to operate efficiently; at 300 MHz, for instance, an antenna would need to be half a meter long. The experimental antennas are as small as one-fiftieth of a wavelength and could shrink further.

In their latest prototype device,* the research team used a metal wire antenna printed on a small square of copper measuring less than 65 millimeters on a side. The antenna is wired to a signal source. Mounted on the back of the square is a “Z element” that acts as a metamaterial — a Z-shaped strip of copper with an inductor (a device that stores energy magnetically) in the center (see photo).

“The purpose of an antenna is to launch energy into free space,” explains NIST engineer Christopher Holloway, “But the problem with antennas that are very small compared to the wavelength is that most of the signal just gets reflected back to the source. The metamaterial makes the antenna behave as if it were much larger than it really is, because the antenna structure stores energy and re-radiates it.” Conventional antenna designs, Holloway says, achieve a similar effect by adding bulky “matching network” components to boost efficiency, but the metamaterial system can be made much smaller. Even more intriguing, Holloway says, “these metamaterials are much more ‘frequency agile.’ It’s possible we could tune them to work at any frequency we want, on the fly,” to a degree not possible with conventional designs.

The Z antennas were designed at the University of Arizona and fabricated and partially measured at Boeing Research & Technology. The power efficiency measurements were carried out at NIST laboratories in Boulder, Colo. The ongoing research is sponsored by the Defense Advanced Research Projects Agency.

Roger-

I'd say this was factual fiction!

Perhaps they are receive-only antennas that use something like an MOS
FET to drive a low impedance cable.

Perhaps the one-fiftieth wavelength antennas were used in the
experiments that failed!

Dear Group: Frank Drake hired me for my first job in radio astronomy.
Years latter, I learned that he was most impressed that I had a first class
FCC commercial license (that type of license is long gone). Did some neat
propagation research in the hills of West Va. (where we did use antennas!)
Prof. Drake had an involved mathematical model that he used to suggest
existence of other people.

The December 1959 paper by Costas made clear the inherent advantages and
disadvantages of wide-bandwidth modulation systems. As others have
observed, narrow bandwidth emissions are most unlikely.

Roy,

Here is a paper describing the feedpoint impedance and how they
counteract the capacitive reactance without the typical matching
network.

http://www.ece.arizona.edu/~ziolkows/research/papers/Metamaterial_Research/Antennas/Ziolko
wski_Erentok_IEEE_Trans_AP_July_2006.pdf

A number of other papers on these antennas are located here:

http://www.ece.arizona.edu/~ziolkows/research/Metamaterial-Engineered%20Antennas.html

I look forward to your feedback and the comments by others on this
subject,

Roger

In fact, commercial Ham antennas with similar efficiencies at similar scales have been around for decades.

Shrinking them further encounters loss accumulating at the 4th power of size. This is a very difficult proposition to beat in stale reporting with the concurrent lack of proven models following after lo' these 4 years. That is pretty sound evidence of these researchers having been lost beyond the precipice of an astronomical plunge in efficiency.

Yeah, yeah, yeah. Now, for the true test of comprehension, answer
this:
What is THE metamaterial?
(cut and paste in response is not an answer, in your own words please,
as YOU understand it)

For extra credit:
What IS metamaterial?
(cut and paste in response is not an answer, in your own words please,
as YOU understand it)

If this cannot be sensibly answered from the accumulation of you
reading of all links and bibliographies offered, then not much is
being offered up in the way of discussion.

And there's another factor, brilliantly illuminated in a short story in Analog magazine years ago. A series of scenes took place, each involving a different alien species in some distant solar system. In each scene a discussion was taking place, involving budgetary restraints and the prohibitive expense of transmitting powerful signals for other civilizations to pick up. Each one, in turn, decided to reduce expenses by listening only. . .

Thanks very much for the additional information. It's very good news indeed, and the first I've heard of anyone being able to do this. My so-far 100% reliable antenna rule of "Small-Broadband-Efficient: Choose Any Two" might finally be broken. My "fiction" judgment was based on the initial description which sounded so much like so many I've heard over the years. I amend it to "Sure looks promising", since it looks like they've finally really attacked one of the fundamental limitations in a way that might bear fruit. A career in electronic equipment product development has taught me that there's a vast distance between getting something to work once in a lab and building them by the thousands out of real parts and having them all work as specified. The path between is full of surprises and obstacles, most of which can be overcome but sometimes some which simply can't. I sure hope this can be developed to the point of practicality. An encouraging factor is that there's a real market for efficient, electrically small antennas in things like RFID tags and keychain remote control units, to name just a couple. This means that money will be available for development.

Only one frequency is reported:
F1. 300 MHz
and two standards of measure are reported:
L1. The square is 30 millimeters on a side.
L2. square of copper measuring less than 65 millimeters on a side.

Obviously not one antenna being described here. Further reading
(courtesy of googling for deeper, less frivolous reporting than puff
piece press releases) reveals another frequency:
F2. 570 MHz

There is a curious and loosely correlated ratio between
F1/L2 and F2/L1.

Next, we consider that there is more to the radiator than the
"metamaterial" - a quite remarkably large and thick disk of solid
copper that appears to be serving the traditional function of
counterpoise.

Barring that last observation, taking the 300 MHz (suggested
excitation) and the stated 65mm physical description that attends this
frequency; and accumulating the meander's length; then that is a 260mm
long monopole (meandering, albeit), with an inductor as center load.

The 300 MHz wavelength is (naturally) 1000mm. A resonant monopole is
typically 250mm.

Several questions come to mind:
1. What is the extra 10mm for?
2. What is the extra inductor for?
3. What is the copper disk (looks to be 1/4 wave in radius) for?
4. What happened to the 1/50th wavelength claim?
5. What virtue of "metamaterial" adds efficiency to what would
ordinarily be 100% efficient with that much copper shown?
6. Who gives a shit?

So far nothing has been written about the radiation resistance of this
"1/50-wave" antenna.

Even if the design eliminates the feedpoint Xc of this electrically
small radiator at the operating frequency, its radiation resistance
could be expected to be miniscule, because the Rr of a radiator
depends on the electrical wavelengths it exposes to space.

The claim that it radiates 95% of the power applied to it may be true,
but needs to evaluated with the radiator as part of an r-f system --
where with very low Rr, much of the available power can be subject to
very high losses before it reaches the radiator.

Hmmm, I'm thinking it could be useful as an element for a frequency agile radar array. Diversity radar?
If current radar detection systems rely on the target detecting an incoming beam at a given pulse rate and frequency, then by varying the frequency and pulse rate constantly, detection would be more difficult.
Computer hardware and software is sufficiently powerful to be capable of processing the target returns at varying frequencies and GPS satellites can provide a frequency locked source for synchronising the transmitter and receiver, so you end up with effectively a stealth active radar system.
A wide band electrically tuned antenna would be essential for such an application. It might even be able to detect stealthy aircraft and ships as they tend to be optimized to absorb/divert frequencies in the most used radar bands.
An electrically controlled frequency agile antenna which forms part of an electrically steerable planar system would also be useful for jamming multiple frequencies and sources. This could turn out to be a somewhat expensive project.

Very useful, though I'm still not clear about using it for HF. I found eBay listing 270364333691 (worth seeing, low cost, good pictures and description), but that shows a thin braid and film that I read might not be adequate for shielding at HF. Low cost is great but I wonder if trying to get good connections to aluminium braid will be more trouble than it's worth, if the worth of a cable with a copper braid isn't that much higher. (Still looking for one). The cable that seems most likely to work based on all I read is a BT2002 cable with a double copper braid over a foam dielectric and stranded core, but the cost is three times higher.

> about what your requirements are.
>

If I went into most places selling cables I'd get laughed at if I took that line, they'd say 'hie me to a research lab, if not an actual nunnery'. :) Not that you're wrong, but if you want a single general purpose cable for HF and VHF especially if stocking it for general sale, then there IS a 'best' cable, defined simply by that which most likely serves the wide range of purposes at a low price. Currently in the UK that cable seems to be RG6; few places like to stock more than one type for RF if they think one will do. Perfectionism is NOT the first base. It's reasonable to expect some standard without being told to either become an expert or use a bell wire and stay in ignorance. RG6 works, but they sell it for VHF/UHF, not RF. I'm not so concerned with moderate losses, but SNR maintained by good shielding matters to me.

I take your point about poor foil/braid shields being worse than good braids. That's partly what drove my question. It seems to me that RG6 in all forms I have found is optimised for VHF and higher. Nothing I've seen either before or after that question has yet convinced me that RG6 is the better choice for HF. I've seen plenty of posts saying it will work, but just as many saying they've seen old RG59 cables doing fine at UHF too.

So far I think I'm likely to go with the more costly double braided BT2002. Most posts I read stated that poor performance was usually due to difficulties connecting firmly to the soft aluminium shield than to the cable's own qualities. I suspect the extra cost for double copper braid will be repaid in easier (soldered) connections and other savings elsewhere, plus a certainty that it is effective at HF. I'm not going to be using it for UHF (although I have done once, it worked ok for a long TV aerial extension), and I've already used it for VHF with good results. Main thing with the BT2002 is that it's old, there might be something directly equivalent made for British Telecom data links now, perhaps thinner, or cheaper, or more flexible, but I don't know how to check for that. I've seen a list of BT type cables but I think it was as old as that cable is.

Last time I got the BT2002 I found it, didn't have to pay for it. The only thing making me wary of it now is that it won't be free this time. :)

You seem to miss the point that one shop's RG6 (or most other RG cables)
may well not be the same as another's. So there is no definitive answer
to you question.

It is also very unlikely that 'good shielding' will have any effect on
SNR in most applications, other than due to increased loss if the
braiding is very very poor, or you are running the cable very close to a
source of broadband interference.

Jeff

Yes, if I was using for UHF and perhaps VHF as they sell it for. But as far
as I know the older UG59 used a braid with better physical coverage and was
specified for HF as well. I'd rather get something this time that has good HF
shielding as priority, so I'm not convinced that RG6 is the right choice. A
bit of extra loss isn't as bad as poor shielding.

Once you get a good grade of RG-6 with the foil and braid, does the quad shield cable really do anything for the home TV usage ? I think it is all just some hype just as the Monster cable is for the audio people. Sort of like the 120 volt line cord being special and costing $ 100 or more for a 6 foot cable. Even it it did something, there is 25 to100 feet of regular old wire to the breaker box.

No, haven't missed that at all. Most of my time is spent looking at all the
RG6's out there and examinng that. Besides, most advice out there implies I
have to buy it and try it to be sure, which is stupid because it's cheaper
and faster to get a better cable! RG6 is specified for UHF, I want HF.

I've been told that braid makes a great deal of difference to common mode
noise pickup, and that while a thin foil and loose braid is fine at UHF it's
not to be expected to do the same for HF.

http://www.abccables.com/info-rg59-vs-rg6.html is one of the more descriptive
texts I read. No RG6 that I have found fits the description given there for
HF. RG59 does though, as does BT2002. I think I'll be going with that BT2002
anyway, never mind the expense. The waste of time trying to avoid it is alone
beginning to look more expensive than the price difference.

The standard for cable tv and satellite instalations is RG6 "quad shield",
which has a less dense braid, but a (almost) 100% aluminum foil shield.

The question is how do you connect to it? Commerical applications use special
crimp on connectors, you can solder it with the proper flux.

A friend brought some Radio Shack screw on PL-259 connectors that work fine
with it, but they are $6 each in the US, and unavailable here.

Most of the things I read suggest that the extra sheilding is only really
useful if you have a strong local signal you want to exclude. More problems
result from poor connections, according to posts by satellite installers,
than from using a cheap foil/braid shield.

As far I can tell from advice on HF, the thin foil doesn't shield as well at
HF as a thicker braid with good physical coverage.

I found an RG6 at low cost with copper braid and Al foil (more likely
metalised plastic film) so I can solder ok with that, but I'm going to be
using this for HF, not UHF, and if anything, I want to include MF signals so
as I mentioned in other posts, I'm not convinced that RG6 is the best choice,
unless it's the only RF cable in the shop. :)

Even if you accept the principle that foil is worse than braid for
common mode signals, where do you think these signals are coming from?
Unless the cables route close to the source of the interference then
your antenna is going to pick it up much more than any difference in
shielding.

I must admit I do not understand the theory that foil is worse than
braid at lower frequencies, foil gives 100% coverage and is usually in
addition to braid. Even if it the thickness of the foil that is in
question, I don't see how, according to the article that you linked to,
it " don't(sic) have the proper type of shielding ".

There may be an issue with terminating foil shields well but that is a
different matter.

That tells you a lot about the people posting. The quad shield is not
to prevent other signals getting in, it's to prevent the ones inside from
getting out.

I'm not in the US, so I don't know if the VHF/UHF TV channels were abandonded
by cable companies in the switch to digital, but you can be sure that any
now unused bandwidth won't stay unused long.

True, but that's why I want it. It's to exclude HF noise made by anything in
the building. The antenna will be several tens of metres away. As the signals
I want are HF and perhaps high MF from that antenna, it seems unlikely that I
should go with a cable whose specs are too loosely defined, and all
interpretations of 'RG6' are now attempts to reduce cost while getting
acceptable performance at UHF.

Well, that's why I'm questioning it here. Like Geoffrey Mendelson said in his
reply in the later thread on RG6 in this group, a lot of the posts I've seen
on the web say more about the posters making them. I think I'll get a better
signal here than on the web at large. No irritating forum signups before
posting, either.. That article does seem to have a few vague contradictions,
but I think the point about a thin foil that is adequate for UHF screening
being inadequate for HF is interesting, and I've seen that point claimed

before. I'm pretty sure I'm not going to get an answer for that from people who are dealing with UHF or fast digital signals, and mainly from an installer's point of view, if the equipment they're using will filter out HF anyway. Their purpose is not the same as mine.

> There may be an issue with terminating foil shields well but that is a
> different matter.
>

I found an RG6 with copper braid, to take care of that. Cheap too, but only if it works. If it doesn't it will be cheaper to go for better cable to start with. I like that BT2002 with the double copper braid, but I'm not yet sure if the difference justifies the cost, though judging by what some places charge for RG6 it probably does..

There also is the question of cost and availablity. I can go to Home Center and buy for about $.50 a meter a decent quality RG6 quad shield. In other places, you should be able to localy source it for less.

Radio type coax requires me to special order it at the local electronics store, and it will be a lot more expensive and less likely to be what I wanted.

I really do miss being in the US able to go into any one of 6 Radio Shack stores near my home and buy RG8x (really just improved RG-58) or RG-8 coax by the foot. It wasn't the best one could buy, it it was "good enough".

I can only guess you situation, but if you can do it, I would just go to a supplier you trust and buy RG6 and see if it works. While I'm sure if you had the right equipment you could find differences in the noise that comes through various RG6 versions, it may not be enough to matter.

Geoff.

Well, that's maybe first choice. Just haven't decided if I'll stump up the
£18 or wait and search a bit longer for more info.

My situation is an HF antenna that will bring a signal from several tens of metres away, into a building with stuff likely to put RF at several frequencies onto the line. I'll filter out what I don't want with a selective 'tuner' eventually, but whether I do that or not I still have to reduce common mode noise that is in same band as signals I want. I'll be using ferrite slugs to reduce this, but I learned that this works by blocking skin-effect carriage of RF signals on the outside of the coax shield, reducing common mode noise by making current in the shield balance that in the core. This implies that when a skin effect carries current down the outside of the shield, but is not equal (and inverse) to current in the core, it must be balanced by current on the inside of the shield instead. In transmissions, I'm told this can turn a shield into an emitter, and though I'm receiving the inverse is true, so I don't want the shield to pick up local noise and feed it to the input via imbalances between shield and core. So if this use of ferrites relies on suppressing signals in skin effect current flow, and HF skin effect thickness are thicker than those for UHF, it seems to follow that a metallised plastic film is too thin. It appears that a shield for HF must be at least twice as thick as the skin effect depth for HF. RG6's foil or metallised plastic seems too thin, and while the braid is thick enough, its physical coverage is poor. I think it's mostly there to ensure continuity of foil as a guard against UHF noise when foil cracks on bending, and as a means to anchor a connection.

302. Cable Shielding Misunderstandings

Newsgroup: rec.radio.amateur.antenna
Date: 2010-01-31 20:10:20 UTC
From: Richard Clark <kb7qhc@comcast.net>
Message-ID: <5uibm55g7p0f7dmdhkvcrrtj5ctfji1q4d@4ax.com>
Source record: 11102

Accumulated from various threads and contributions that demonstrates
anxiety, not research:

>As far I can tell from advice on HF, the thin foil doesn't shield as well at
>HF as a thicker braid with good physical coverage.

It sounds like you should stop listening to advice on HF.

>I found an RG6 at low cost with copper braid and Al foil (more likely
>metalised plastic film)

...and hence mostly likely NOT RG6. RG-anything is barely more than a
public domain trademark. This been hammered to death already so any
appeal to nomenclature should be confined solely to the physical
attributes of wire radius and shield inner radius; and NOT the number
of shields, NOT the coverage of the shield, NOT the property of the
wire being stranded or solid, NOT the property of the shield being al
vs. cu. Everyone of those prohibited-for-discussion characteristics
varies between manufacturers sharing the same nomenclature.

>The standard for cable tv and satellite instalations is RG6 "quad shield",
>which has a less dense braid, but a (almost) 100% aluminum foil shield.

Foil shield is a gap filler, NOT a conductor in the conventional sense
of long runs. There are no coaxial cables that have only a foil
shield (a plastic carrier of a metal deposition) that are useful for
any antenna work. Hence, the property of foil alone does not bring
any useful quality to the discussion.

>As far I can tell from advice on HF, the thin foil doesn't shield as well at
>HF as a thicker braid with good physical coverage.

Abysmal sources of information should not be returned to. "Thin foil"
is a gap filler, not a shield.

>Besides, most advice out there implies I
>have to buy it and try it to be sure, which is stupid because it's cheaper
>and faster to get a better cable! RG6 is specified for UHF, I want HF.

RG6 does not have a specification for frequency ranges outside of
loss. In that regard, RG6 is eminently preferable for use at HF over
UHF for that one consideration alone. There are cables of other
physical geometries (about the only thing that counts in this
discussion) that exceed the performance of generic RG6.

>http://www.abccables.com/info-rg59-vs-rg6.html is one of the more descriptive
>texts I read.

Interesting? Quite banal, in fact, when one stumbles over such
statements as:
"A basic rule of thumb is to use RG6 for any
Rapid Frequencies, and use RG59 for
video frequencies."
Now there's an authoritative standard you can take to the bank (if it
is AIG). Perhaps they meant "Vapid Frequencies."

>I must admit I do not understand the theory that foil is worse than
>braid at lower frequencies, foil gives 100% coverage and is usually in
>addition to braid. Even if it the thickness of the foil that is in
>question, I don't see how, according to the article that you linked to,
>it " don't(sic) have the proper type of shielding ".

Foil, as pointed out, is in addition to standard shielding. Foil
bridges the gaps between the wires composing the weave of the shield.
Those bridges are highly conductive over the very short distance
between adjacent wires, but as a conductor, foil is miserable as a
sole conductor. That is why foil shields that are the sole shield
have what is called a "drain wire" running the length of the cable. It
is quite obvious that such cables have enormous loss per foot in
transverse mode, but these shielded cables do not operate in that
fashion as they are almost exclusively supporting paired conductors
(twisted pairs that are the signal carriers). Hence, these
applications of foil/drain-wire are limited to low signal use where
the shield will encounter small fields. Even then, they can be
marginal.

>That article does seem to have a few vague contradictions,
>but I think the point about a thin foil that is adequate for UHF screening
>being inadequate for HF is interesting, and I've seen that point claimed
>before.

In coaxial application, the performance of the foil is limited to its
thickness, which in turn can be penetrated by low frequencies. We
know this as an example of penetration depth. The surrounding wire is
probably 10 to 100 to 1000 times thicker in that regard. The wire
will always satisfy most typical applications (VLF and up) and where
it would not is found in "coverage." Such issues are very rare and
are not elevated to important simply because you are straining to
catch a weak signal.

Even with this shortfall, one has to consider. On the one hand you
have a 90% coverage cable that gets signal into it. You add a poor
conductor like a metal deposition plastic covering (aka foil) and it
reduces that specific leakage by 3dB. To buy that 3dB in additional
conventional wire coverage may boost the product cost 10% whereas
adding a foil boosts cost only 1%. By reputation around the pickle
barrel, the foil is still a poor solution, but in a particular
application it bought you 3dB that you might have walked away from.

This, of course, is a fantasy scenario to illustrate how a technical
decision is weighed against cost and need. Unfortunately this fantasy

scenario exceeds the technical discussion found in:

>I like that BT2002 with the double copper braid, but I'm not yet sure
>if the difference justifies the cost

Sole cost based decisions for technical problems rarely prove useful.
You are going to have to decide whether you can accept the performance
you thought you paid for, or pay for the performance you need. As you
have not actually specified any quantitative characteristic, you are
facing either disappointment or illusion.

Ok, if I take that with the point about lower HF loss in RG6, it seems that my easiest option of a copper-braid RG6 will be good, but this still begs one question: If BT are using BT2002 double-braided copper and no foil, at greater cost, what does it do for them that RG6 will not do? Would it be a matter of transmission power, or something else?

Richard has debunked much of the FUD about the foil/braid outer conductor.

Not wanting to hijack the thread, but for all the paranoia about whether the outer conductor works properly and at what freqeuncies, the discussion has ignored the risk of poorer performance at low HF for such cables with CCS inner conductors if the cladding is inadequate.

This effect does not seem to worry most ham users of CCS ladder line, so perhaps ignoring it for RG6 or RG59 is in keeping with that.

I use RG6 selectively, selected cable and selected connectors on selected applications. There is potentially a good match, prospect of low cost and good performance.

Inspect a sample of the cable you are considering, whether it is RG59 or RG6, or any no-name cable for that matter. If through braid leakage is critical to your application, you are more likely to find no-name RG59 with higher through braid leakage than RG6.

Owen

I just wanted to focus on one thing at a time, given that types of RG6 seem
to proliferate like types of dog. One thing I'm asking sellers, if it's not
clearly described, is if the core is magnetic or otherwise obviously steel.
I've seen cables that are, and I already intend to avoid them. I restricted
my questions to those where I sas NOT sure of subsequent action.

>matter of transmission power, or something else?

One issue which may be relevant in some applications (transmitters and
repeaters) is internally-generated cable noise.

Foil-and-braid cable has developed a somewhat evil reputation among
repeater operators. The story, as I have been told it, is that the
braid, and the conductive layer on the foil, don't make particularly
good (or continuous) contact. As RF power flows through the cable,
some of the current can jump back and forth between braid and foil,
through imperfect connections each time. This leads to some amount of
discontinuity in the current flow (diodic junction effects or
"micro-arcing") and rectifies a small amount of the RF power into
broadband noise. The same effect might be capable of generating
intermodulation noise, if the cable is carrying two or more strong
signals at the same time.

In many applications this effect is irrelevant. In a duplex
application (e.g. an FM repeater) it can be nasty... the broadband
noise from the transmit channel goes right through the duplexer stage
into the receiver, and can swamp out the desired incoming signal. You
can lose several dB of receiver sensitivity due to this effect.

For this reason, repeater builders prefer to use a non-foil-shielded
cable. Cables with double silver-plated copper braid shields are
popular, as are heliax-type semi-hardline cables.

This is called confirmatorial bias which means you justify a thought
on the basis of having found a source that repeats it back to you.

You still haven't offered the quantification of one characteristic you
want to achieve other than cost. Why is this? Clearly a cost basis
is wildly off the rails and you offer nothing else to compete against
its failure.

Face up to the disillusion being presented in this painted into the
corner scenario you are in. The cheapest cable will probably work as
best as any sensible solution has to offer, simply because your
perceived situation hasn't any prospect of being solved by that choice
of line, or any other.

Hi Dave,

I've seen this exact same statement expressed in regard to problems
introduced by the weave of wires in the shield of coax. And yet your
story teller relates that doubling the amount of shielding with woven
wires is the preferred solution.

Given the elaborate logic one must invest their faith in, for the one
explanation to make sense in regard to foil and then to be wholly
unremarkable in woven wire seems to make this rather apocryphal.

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

There seems to be two different meanings of "foil" in this discussion.

Most of the criticism seems to have been about "foil" made from aluminized plastic. I'd agree this is very dubious because the effective thickness of metal is unknown, especially in low-cost cables. The presence of a so-called drain wire is also an indication that it's difficult to make direct contact with the metal in the shield.

However, "foil" can also mean a thin but solid metal sheet. When applied as an overlapping wrap of >360deg, this kind of "foil" has close to perfect shielding properties at HF and above. Its main weakness is that the metal can tear if the cable is bent too sharply, and the main purpose of the braided copper cover is to bridge any resulting gaps. Both copper and aluminium foil-covered cables are available, and copper will obviously provide a more reliable contact between a connector and the shield.

Another kind of solid metal "foil" is bonded onto the outside of the centre insulation. I've only ever seen this in aluminium; the foil is extremely thin and solidly bonded to the polyethylene, making it very vulnerable to damage by bending. A braided cover is provided, but once again there can be problems with connector assembly.

These points are confirmed by Owen, VK1OD at:
http://www.vk1od.net/transmissionline/RG6/index.htm

In this wet climate I wouldn't ever use a cable containing aluminium;
but Australia's different, of course.

Finally, beware of ALL "RG" designations. The military RG cable
specifications have been obsolete for many years and the carpetbaggers
have moved in. "RG8" was the first to fall, and "RG6" can mean both
anything and nothing.

Even in the days of MIL specs, "RG58" covered several different types of
cable - the copper could be either bare or tinned, the centre conductor
either solid or stranded - so it has always been necessary to check what
kind of construction you were buying. In modern times you also need to
check the quality.

About the only "RG" cables I'd trust today without seeing a sample are
RG213 and 214, and only from a trusted supplier.

No. It's called 'go see for yourself and tell me based on YOUR judgement if it's worth revisiting'. If all I wanted was a pat on the head I wouldn't even have provided a link. Either that info has technical merit, or it doesn't in which case perhaps you should berate THEM and not me! You expect me to fully understand details beyond need, yet you won't even take a look at something signposted right in front of you is an adequate source of info to learn from. If you can't do that much, why should I trust your judgement? I'll make up my own mind anyway. Between my efforts, and the other posts here, I have got my answers.

> Face up to the disillusion being presented in this painted into the
> corner scenario you are in. The cheapest cable will probably work as
> best as any sensible solution has to offer, simply because your

> of line, or any other.
>

Well, that's just nonsense. Grandstanding nonsense at that. You just baldly stated that no cable can fix whatever my problem might be, purely because YOU can't see what it is. You're painting me into a corner. I'm trying to get out of one. There's no technical point in what you just said. At least I try. With your knowledge, you should know better.

Other people here, (and in the pages I linked to but you didn't apparently see) have shown that foil can be so bad, either from tearing, or dubious contact, that it's unwise to use it except in fixed situations where you know it will be ok, and not for someone who is likely to want to reuse a cable while trying new ideas, or to grab more off the reel to try something else. I've seen that RG6 types vary so much that there's no point citing its name. Considering I never used to, and already knew that 75 ohms is a result of precisely controlled sizes and manufacturing tolerances, I was probably better off before I saw people telling me that distinctions between RG6 and RG59 were important. Their context isn't the same as mine. My needs are more likely to be satisfied by a BT data coax than a satellite coax.

Cheap cable meant for satellite, which IS wht I'll get if I take your suggestion of buying the cheapest cable called RG6, is a sure recipe for crappage. Cheap satellite signal cable isn't meant to perform beyond its specific purpose, and I never expect it to. Of course I'd end up disillusioned AND disappointed if I chose to use it as general purpose RF cable. But what did you really want? To help? Or to set me up for failure as part of some bizarre exercise? I guess only you can know the answer to that, I don't really care. Considering the cost of any 'RG6' that really qualifies as adequate, i.e. solid metal foil wrapped by one braid of tightly covering copper, there's little choice between that and the BT2002 I found, and the latter will take punishment better, if punishment is the order of the day.

I'll be choosing a double-braided copper, each braid of the '95% coverage' type, close and compact. I don't care that it costs twice as much, I can trust it to have decent screening for any circumstances I'm likely to meet from AF to UHF, and it's thin and flexible, and I can expect it to take weather and rough handling and be fit for reuse when I want to do that. And because BT use so much of it I can hitch a ride on the economy of scale that drives the price down. For what it is, it's better value than the cheapest.

End of discussion.

You would use a magnifying glass to examine an antenna in your dongle?
:)

Quite true. I've asked several times, as have others. So to do it
once again, beyond cost: what is YOUR problem and not someone else's'
that you overheard?

We have your dozen or more suppositions filtered through anonymous and
linked-to sources of indifferent quality that each in their own right
have issues with a spectrum of cable types - but none of them have
been identified as YOUR problem except in generalized, anticipated
anxiety. Can you state one simple quantified characteristic you
currently experience that we can offer a comment to?

As a matter of interest why are you looking at 75ohm cable, when most people and equipment use 50ohm.

I've posted more than enough. If that wasn't enough to show what I wanted (I described it repeatedly in posts dating back over a month), then any more is just noise so I won't go there.

One thing I will say: Most of the practical guides I read as a kid were a lot more vague than I have been, yet I was expected to learn from those. Yet now you say you can't deduce from my posts what I was trying to do? With all your knowledge to fill in gaps in what you see? Strange. I'll stop now because if what I said isn't beeing seen, I don't want to compound that by writing another word.

Good point, though last I read of that, it was the other way round. :)
(Depends on context). At least, most times I had a device that needed RF
coax, it specified 75 ohms if it didn't come with cables made for it. In my
current case, it's not clearly known what other impedances are involved in
an SWL setup, but they're almost certainly higher than 75 ohms, so going for
a 50 ohm coax seems unwise.

>difficult to make direct contact with the metal in the shield.

Actually, the drain wire is not specifically needed for termination,
but having said that, it is needed for termination - in a practical
sense. The drain wire does not run the length of the cable simply to
provide a handy length of wire available at any arbitrary point of
cut. The drain wire is "so-called" because it serves as a current
drain. It is a necessary component to the electrical design much as
the "so-called" drain lead on an FET is.

The foil has an atrocious conductivity for any significant length. If
it were to be relied upon alone, you could as easily assign it the
name of distributed resistor instead of shield (and yet even a
distributed resistor would satisfy some purpose of shielding).

The drain wire insures that this significant length of atrocious
conductivity is no greater than half the circumference of the inner
insulated wire. At this length, the foil path resistance is a quite
suitably low resistance.

The sense of drain, is electrostatic drain. If the term appears to be
"so-called" it is by purpose and historical application.

>However, "foil" can also mean a thin but solid metal sheet. When applied

>will obviously provide a more reliable contact between a connector and
>the shield.

Every cable has what is called its minimum turn radius. In use, this
can be violated and the physical and electrical properties can become

compromised. This is not a fault of design.

That a user can put a cable to misfortune is not remarkable insight, but attributing the tear in this foil to becoming a great misfortune seems to be hysterical as that tear is drawing down the shield coverage from 100% to 99.9999999% except at one specific and distraught bend where it might actually reduce it to 96% (the native coverage of the woven shield that embraces it) for an eighth inch. It is very hard to imagine a situation where this local discontinuity serves to bring down an entire system when it is a design redundancy. The user having violated the minimum radius rule should be more concerned with the inner wire migration through insulation and causing a short - a vastly higher probability of an issue of greater concern. Most Hams are quite aware of that consequence, and it alone (if nothing other) motivates them to observe the minimum bend radius prohibition.

Those Hams who are not aware of this consequence lead a superstitious existence where failure arrives by the fault of some mysterious and elaborate agency:

I have heard these stories of torn foil for years. And yet each and every one of them has been testimonial, not research based in their having been the cause of misfortune. Evidence would demand that the entire length of jacket and woven shield be stripped off the cable in some form of ritual much like an autopsy. That operation alone is suggestive of general destruction, a self fulfilling prophecy once you get down to the fragile foil layer.

This level of examination is something only a producer would embark upon, and once they discovered a systemic failure, they would resolve it (cynics can chime in here with their chorus of "no they wouldn't"). A Ham would look at a kink in a cable, open it up, discover torn foil, and it would be immediate proof of the problem. Simply fill in the blank of what that problem is, and add that to the list of ills that proceeds from using foil shielded cable.

Now, if some scribbler wants to invest foil with toxicity for their current situation, it might do to follow the lead of that foil being (in flexion at a rotor, for instance) a source of triboelectricity. Ponder the genesis of the following observation:
>Another kind of solid metal "foil" is bonded onto the outside of the
>centre insulation.
which serves to resolve that (the manufactures DO perform autopsies and they DO provide resolutions).

If you turn to Wikipedia to consult what the term triboelectric means (few here are going to have encountered it knowingly), it will only be loosely descriptive, but sufficiently so. A more suitable introduction can be found at:
http://www.systemswire.com/low-noise-triboelectric-cable.html
One extract can be informative:

"The size of the triboelectric voltage spikes
in the cable is very much a function of the materials
selected by the cable designers. Copper and foamed
polyethylene, for instance, are two of the lowest
triboelectric generators available today. Adding
conductive low-noise layers can also reduce the
noise levels from tens of milivolts to the microvolt
range. The cable noise reduction noise occurs as
a result of draining the triboelectric induced charge
away from the wire insulation."
... and we encounter that "so-called drain" once again.

Virtually all radio equipment is standardized on 50 ohms, with the
exception of CATV etc.

Any receiving equipment you get will almost certainly have a 50 ohm
(nominal!) input, so any higher antenna impedances will need to be
matched back to 50ohms anyway. How much loss you will encounter by using
75ohm cable will depend on the actual set up.

Jeff

Apparently no-one knows the impedance of a Sangean ATS-909 radio, I've asked several people, at least one of whom specialises in modifying that radio. Looks like 1K is best guess based on schematic. Loss won't bother me so much as SNR. Several people advised that a 15 foot vertical whip is likely to overload the input so loss is not my main concern.

On the basis of that logic, what possible use could there be for 400 ohm transmission line, and why then is it so very popular?

In the case of the OP's questions, IIRC they relate to a RO application.

To enlighten you, high performance noise optimised ham receivers for microwave bands are oftenm if not usually designed for a specific input impedance that is quite different to 50 ohms... yet we use them with 50 ohm transmission linees.

If you think the choice of 50 ohm line is a no-brainer, you are probably right.

Quality of product is an issue, but the type of 'foil' you describe, and as part of a system of braid and foil isn't necessarily as poor as you intimate.

The better ones are quite tough, in fact one might desribe them as tenacious when trying to terminate cables, and if you look carefully, they are circumfrentially closed.

As I said earlier, and I think you are agreed Ian, cable bears inspection. It does take experience to develop the skills and knowledge to be competent. Above all objectivity is important. I gauge a certain bias in the OP's approach... but I could be wrong.

Owen

PS: Sitting here is unwanted rain from day to day (I am trying to build a shed at my new place), I am a bit amused at the throwaway line about Australian weather. I visited my old house a few days ago, it is about 150km away, and dry as. However, Australia ranges from tropical rainforest to dry desert and I would not install any form of coax without adequate protection from water.

I know from work experience that the products of aluminium corrosion can play havoc with IMD... but then if IMD performance was critical (eg a communal repeater site), you wouldn't use RG6 in any form, or probably even braided copper for antenna runs, you would look at solid copper outer conductor and DIN coax connectors.

Which all shows that there isn't a single "best" coax for all applications.

Worse..
Several cable channels overlap the aviation VHF band, and as one might imagine, the FCC comes down on the cable operator pretty quick if their physical plant is leaking any significant power at those frequencies.

As noted elsewhere, the last thing the cable operator wants is to discover that some cable inside a customer's house is radiating. The cable operator is responsible for signal leakage all the way to the point of use (e.g. the RF input to the TV).

This is unlike the regulated telephone company, where there's a clear "demarcation point" that separates the responsibility (it's even called the "demarc" colloquially.. it's at the cable point of entry to the house, and has a phone jack and plug installed). For phone stuff, if there's a problem, and they come out, and unplug the demarc, and the problem goes away, YOU get to fix it, because it's on YOUR side of the line.

It's a sort of trade.. the cable company is very lightly regulated, and can offer services and such all the way into your house, but in exchange, they're also responsible.

1K is just a guess as it is just one component in the antenna input
circuit.

Also, nobody observed that the input impedance of the radio can vary
significantly with the setting of the "RF Gain" control.

Crude measurements on a DX-398 show the impedance near 85 ohms at 'max'
gain and near 280 ohms at 'min' gain. The measurements were crude and
the error could be 20%. Use these numbers with caution.

There are no guarantees that the input impedance does not change with
frequency, either.

The Sangean ATS-909 appears to operate no higher than 30 MHz. In the HF range, antenna efficiency and transmission line mismatch have no significant effect on the signal/noise ratio (unless the system is exceptionally lossy and/or the receiver exceptionally noisy, neither very likely), hence they don't affect your ability to hear stations.

Roy Lewallen, W7EL

It seems very strange that you are taking things to the ultimate when
considering coax cable, whilst considering using a very inferior
portable radio for your reception!!

Very well, let me re-phrase: the presence of a so-called drain wire can
be taken as an indication that the metalized plastic shield has poor
electrical conductivity and is not suitable for RF applications.

Manufacturers are fully entitled to specify a minimum bending radius.
What's important here is the *result* of bending the cable at a
progressively decreasing radius. A braided shield will slip and stretch
to relieve the stresses, and will often survive quite excessive bending
without breakage of strands; it will then recover leaving relatively
little disturbance.

In contrast, a foil shield has a very sharp failure threshold, beyond
which it will be torn apart; see below.

Those are two separate problems. The "issue of greater concern" is the
simply the one that happens first; but without detailed knowledge of
each specific installation it's impossible to predict which one that may
be.

>Most Hams are quite aware of that consequence, and it alone (if

>some form of ritual much like an autopsy.

Here is that story. The cable in question was semi-airspaced with a shield made from solid copper foil in a >360deg wrap, overlaid by open-weave copper braid. Having experienced problems with fluctuating VSWR in a rotor loop, I removed that entire section of cable - and yes, indeed I did 'autopsy' it.

>
>much like an autopsy. That operation alone is suggestive of general
>destruction, a self fulfilling prophecy once you get down to the
>fragile foil layer.
>
Rubbish.

The cable jacket was carefully removed by slitting along its length and gently peeling it off. In the two sections close to where the rotor loop had been anchored, the foil shield had been torn circumferentially into several isolated segments, each a few inches long. The overlying braid was not broken, and was only slightly disturbed by the surgeon's knife.

Such was the objective evidence.

My deductions were that most of the repeated bending of the rotor loop had been concentrated into those two sections. As for the VSWR fluctuations, it seemed that the outer braid had not made sufficiently good contact to bridge over the breaks in the foil when the antenna was being rotated. I considered both the observed VSWR problem and the implied shielding problem to be important because the system was carrying 1kW at 432MHz.

I accept that these problems were entirely due to my poor installation technique. I now try to distribute the bending more evenly along the entire length of any rotor loop, but it isn't easy. Therefore I prefer to use cables that have some tolerance of excessive bending if it should occur.

>This level of examination is something only a producer would embark
>upon, and once they discovered a systemic failure, they would resolve
>it (cynics can chime in here with their chorus of "no they wouldn't").

No, they wouldn't. They would simply state that this type of cable was not designed for repeated flexing at close to the minimum bend radius. I fully accept that; what I don't like is the drastic mode of failure in which the foil tears completely apart.

In particular, I don't like the type of cable in which the foil shield is solidly bonded to the underlying PE, because there is no possibility of 'slip' to relieve the bending stresses.

In practice, hams have to use whatever is most cost-effective and there is no doubt that solid copper foil has excellent EM shielding properties, so long as that shield remains undisturbed. For a rotor

loop, one has to balance the risk of tearing the shield against the disadvantages of splicing in a section of more flexible and tolerant cable such as RG213.

More modern low-loss cables have both the solid metal foil shield and a heavier cover of braid to act as backup.

>A Ham would look at a kink in a cable, open it up, discover torn foil,
>and it would be immediate proof of the problem. Simply fill in the
>blank of what that problem is, and add that to the list of ills that
>proceeds from using foil shielded cable.
>
None of us was talking about a severe "kink", only about moderately excessive bending.

Although I only had that one experience of failure (and didn't let it happen again), I did take the trouble to find out what had caused it. Several other hams have related similar experiences with those kinds of foil shielded cable. I still use them where low loss is important, but treat them much more carefully than braid shielded cables like RG213.

Not really. A few tens of metres of cable whose cost is not more than 3 times the cheapest of satellite coaxes, and whose total cost is less than half the lowest cost of that radio when found second-hand, is hardly overdoing it.

I think the point is that radio is very much under-doing it!!!

Why are you so set against that radio? A lot of people like it (some of them
enough to modify it rather than replace it). What do you recommend? And how
much would it cost? This thread wasn't about that radio but this is worth
pursuing, you seem to have a strong feeling about it. I just bought it
because it seemed like a good cheap base to start from. (Not cheap if I'd had
to buy new, but I purposely avoided that).

Further, the ATS-909 is a fairly old design. Not many appear used on eBay,
and new ones still sell for what I think are excessive prices, from Germany,
Japan and elsewhere. Bad radios surely get sold on as fast as people can
pass them off on someone else. They're unlikely to be in shorter supply
secondhand than new, when they're as old a design as this one is, and very
few second-hand ones remain unsold when an auction ends. I'm not trying to
correlate buyers opinions with the finer points of radio engineering, but it
remains a fact that people would rather keep them and use them than sell them
on, which is fairly convincing as an argument to get one if the price is
good, so I got one. Had to wait a few months too, for an auction that had low
competition, but I think it was worth it. A lot of people documented
modifications, suggesting an enthusiastic technically adept following. That
is one of the things that helped me decide to get one. It means I'm not
reliant on one supplier for info or advice if I need to fix or modify it.

Really poor radios don't go through what I just decribed, they sink without trace instead of surviving for over a decade with such deep involvement from so many of their users.

That technically adept following could not provide any useful
information on the input impedance. While actually knowing the impedance
may not be of much value in your endeavors, given the availability of
the schematic, someone could have modeled the input in Spice.

That
> is one of the things that helped me decide to get one. It means I'm not

A really good radio probably doesn't need a bunch of modifications to
deal with deficiencies.

Some radios hang around because they were built in large volumes.
Quality and performance may mean little.

The point that was made is your radio does not really warrant the effort
your are putting into the antenna. Any variety of quick and easy
antennas may give you adequate results.

So, here is what I see.
1) Worrying about the radio's input impedance is of little value
2) The choice of coax won't make much difference - performance wise, but
copper braid is much easier to solder to.
3) A simple wire antenna at the end of the coax should be sufficient
4) A balun (or un-un for the picky) between the antenna and coax is
probably worthwhile. 9:1 or 10:1 won't make any difference.
5) Figure out what you are going to do about lightning protection.
6) Rather than spend weeks sorting out the details, string up some wire
and listen to the radio.

On the other hand, I've been told that a good RF ground and a well-sited antenna make more difference than anything else. Who cares about the radio, I can change that. If I don't at least try to get the antenna right, what would be the point of that change in radio? Where I live I'm unlikely to ever get much, but spending what amounts to a couple of weeks food money on trying is worth a go.

> So, here is what I see.
> 1) Worrying about the radio's input impedance is of little value

Of course. Wasn't me who was worrying about it, once I learned a bit about it, some weeks back. I recently pointed out that striving to use 50 ohms for an SWL setup that had undetermined impedances didn't matter to me. Am I wrong both ways?

> 2) The choice of coax won't make much difference - performance wise, but
> copper braid is much easier to solder to.

True. This is something I pointed out, several times. I also pointed out that given the want to try things, a cable that can be reliably reused is better than one that can't, so a fragile cheap foil screened cable is more trouble than its worth.

> 3) A simple wire antenna at the end of the coax should be sufficient

Maybe. I'll be trying that. There's no room out there to run it without bringing it close to buldings so to get anything decent it's going to have to be vertical, so that immediately has a few demands. Can't just shove it up there, it has to be safe. Tenants tend to have binding conditions for putting up stuff like that too.

> 4) A balun (or un-un for the picky) between the antenna and coax is
> probably worthwhile. 9:1 or 10:1 won't make any difference.

I intend to try one. The exact winding ratio doesn't bother me that much. What bothers me is that if I don't mention one someone does, and if I do, I'm told I shouldn't use one. The degree of contradiction I see suggests I'm not the only one with some rather vague ideas. I read posts by John Doty that have persisted a while online in several places since he wrote them. They make sense, so I'll try them. They basically aim to reduce peaks and nulls in

sensitivity for various points in the HF bands.

> 5) Figure out what you are going to do about lightning protection.

Already have. It will go direct from antenna to ground through a winding, there will be no direct current link from antenna to coax. The coax also will have a 1:1 ferrite transformer at the receiver end.

> 6) Rather than spend weeks sorting out the details, string up some wire
> and listen to the radio.
>

A simple wire direct to the radio doesn't help here. I'm in a basement, in an inner city valley. Too much building around me, too much RFI, and too much scaffolding too, major works being done to the building by the landlords. Until I can get some undisturbed access to the back yard to wire an antenna, I have no choice BUT to think of what I can do. The moment actually trying stuff becomes easier than living with that and reading and posting online, then I'll do it. I've bought a few things, coax, toroids, a cheap whip mast, but there's not much I can do out there with anything yet.

One thing I've learned is that for every bit of informed advice, a bit of informed contradictory advice will be found. Considering how easily people give vent to it, it seems wise to ask and watch the answers and make up my own mind. I also prefer to measure three times and cut once. It's usually cheaper. I have plenty of time and not much money.

It is really more the difference in consideration between the coax and
the radio that strikes me. You are making a huge fuss over the coax, but
appear to have little consideration over the radio which is a far more
important issue. You seem to be set on the Sagen when it is is far from
the best solution, but nit picking over the coax, which in reality most
likely won't make a shred of difference.

It is a perfectly adequate radio for what it was designed to be; a
portable that you take away on holiday to listen to BBC world service
on, but as for using it for anything more it is lacking.

Even you admitted in an earlier post that it was overloaded by anything
more than a whip antenna!!

You would be far better off buying a dedicated HF receiver or a
transceiver with a far superior performance. They are available on Ebay
as well.

Jeff

Lacking what, specifically? I wanted a general purpose radio with full AM coverage to 30 MHz, and I wanted it to be cheap and portable. Then I wanted to give it a decent chance of getting signals when I'm not carrying it around.

As for a radio that that is only fit for getting BBC World Service, are you sure you're not confusing the ATS-909 with whatever Sangean's original was, as cloned by Roberts with model R9921? That really IS a basic radio designed for that purpose, the ATS-909 does more.

> Even you admitted in an earlier post that it was overloaded by anything

Not the point. It's easier to attenuate than to do almost anything else. Even the radio itself can do that.

Chiming in late on this one.

The antenna isn't usually the limiting factor on modern radios. You'll likely do as well with a random wire as a seriously engineered system. Since you're only receiving, this is the case.

If you are wanting 500 KHz to 30 MHz, and you want full coverage, you'll be hard pressed to beat a random length dipole and maybe give yourself a little tuning cap on your end if you like. Just put up as much wire as your space will permit, and there you go. This assumes that you use ladder line to feed, not coax. For such a wide range antenna, ladder line is the way to go.

That's going to wring out just about the last bit of performance you can expect, unless you want to go to the bitter edge and construct directional antennas. At the 500 KHz end, that will be a tad difficult.

Now for your application, the performance difference between a chunk of wire, my random length dipole, and some directional gastraphagus will be surprisingly little.

Use, or do not use the advice.

Hi Mike,

With the CM performance being tied to foil application, such a
non-starter is bound to have only the whisp of academic research into
it if you expect to find test numbers. On the other hand, there's
sure to be a forest fire of testimonials.

To help in your search, try googling "cable transfer impedance." The
first page of responses should have a wealth of information.

Yes, but you were not talking about the other bands that it covers, you
only mentioned HF.

So why are you so worried about the co-ax and SNR, if you add an
attenuator in order to make the radio work properly you will also
attenuate any interference (and degrade your SNR).

Virtually any comms receiver will give you coverage of AM to 30MHz, many
also have Band 2 vhf as well, they are too numerous to mention, but have
a look at this link and pick the ones that actuall have good RF performance:

http://www.eham.net/reviews/products/8

Not that I know of, I only saw this one:
http://www.bluejeanscable.com/articles/shielding.htm
It even describes cable transfer impedance so I guess it IS useful for other
than 'telling me what I want to hear'. :)

I just went for braided BT2002 because I know I can reuse it. I originally
found some in a telephone exchange skip, and had used it to extend UHF TV
antenna when I had a TV, many years ago, and later for a VHF dipole. I know
that a good braid covering is good for strong AF, so it seemes highly likely
that it will work on HF just as well if it's that good on frequencies on
either end of it.

>

Because I want to reduce the noise from stuff in the bulding compared to
whatever hits the whip antenna. Sure, attenuation might reduce SNR in a noisy
resistance (or subsequent gain stage) but NOT due to due to simple shrinkage
of scale (R = Ratio...), but that's why I want to get the SNR higher to start
with. It's the separation of internal noise signals from external wanted
signals that matters, same as for anyone using coax. Surely it's not suddenly
wrong because I'm doing it? If so, this isn't about science anymore.

Thanks, that will be useful. The ATS-909 is just a starting point. I want to
have tried it, even if I just sell it on. (Was why I bought it used, that way
I won't lose out).

349. New AR Club - Ant Loc Near Xformer?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-02-03 18:59:20 UTC
From: KE5WZY <KE5WZY.5afb839@radiobanter.com>
Message-ID: <KE5WZY.5afb839@radiobanter.com>
Source record: 11012

Greetings! We are starting a new club: LARC (Library Amateur Radio Club) of Kingfisher Oklahoma. I managed to scounge three ten foot sections from the local phone company an antenna tower base, mid-section and a top section that comes to a point at the top with a hollow pipe. Before I go through all the trouble to locate the antenna, probably against the side of the library and anchor it to the roof, I need to know if anyone has ever had any trouble with a buiding transformer as a potential cause for RF interference. The transformer sits on the ground near the trash recepticle. The ideal location for keeping the tower from becoming obvious, is about 10 foot from the transformer. Keeping in mind the antenna will be mounted at the top of the 30 foot tower, has anyone ever had experience with putting antennas so close to the power transformer?

Of course it has no technical merit, it is just words! Some of them are pretty ambiguous too, like that "video Frequencies" bit. Are the video frequencies they refer to The frequencies that television signals are broadcast or are tehy the frequencies that a video signal uses. THere is a difference.

There's more. From that paragraph above, your not asking us to do your research for you, are you?

Perhaps there is a reason. It isn't terribly important at all.

> Looks like 1K is best guess based on schematic. Loss won't bother me so much
> as SNR. Several people advised that a 15 foot vertical whip is likely to
> overload the input so loss is not my main concern.

Not to be overly precise, but the whip won't overload your radio, strong signals might. Those little radios are pretty sensitive.

So what are you trying to do here, aside from get an external signal into a radio? If you want to have an audiophile grade antenna system, you need to go out and get some good hardline coax*. You can also make some measurements to determine the exact input impedance of your radio, then construct a balun to match it to the rest of the system. If measurement isn't your thing, you can probably get by with a 9:1 balun, as a back of the envelope calculation.

Then if you can put them in, you need around 120 radials that you use for the ground on your antenna. You can either elevate them, lay them on the ground, or shallow bury them. If you have a wife the third option is probably what you want to do.

There are other little tweaks, such as silver contacts, a good quality tuner, and probably some I haven't thought about yet. Some still hold out for low oxygen copper.

Do all that, and you can still do pretty close to the results with a long wire hanging out of your window.

Now if you get a communications grade radio, some of my less tongue in cheek suggestions might help more. But make no mistake, you are deep into the world of diminishing returns.

note 1.

Coolest hardline I ever saw was at a TV station. It was about a foot in diameter on the jacket, and I didn't see the center conductor, but my best guess is that it was around 2 inches in diameter.

note 2.

I'm not trying to be rude, but you've been getting some good info in here, you're just not taking it. Reminds me of some of the students coming out of college these days with a nice fresh bachelor's degree. They don't accept input, and think they should be promoted for showing up on time.

It's much better to see numbers than what some website is telling you.
There are a lot of really smart people in here, and yes, if you do
something that isn't right, you're going to hear about it.

I thiink you'll find that these sites that don't argure with you are
happy when you buy something from them. But it's your call.

Which is why I think no-one stated it too. One person here said it wasn't
stated perhaps because no-one I suggested was adept was actually adept enough
to do it. These are the contradictions I keep seeing. They tend to gravitate
around a poster's ideas as pecived by a reader, rather than by science. I
think you're right in this case, so I'm not arguing.

Yes. Which is why I'm looking at getting signals from outside rather than
inside. I don't mind losses so much.

Going to try that. Winding enamelled wire onto a few bought ferrite torroids
isn't exactly hard work. There will be one at the antenna end too.

Radials, yes, where I have room for them. I don't have any need for 'OFC'
wire, in anything. Or silver, come to that.. Maybe if I met a warewolf? Or is
it vampires? Silver was supposed to be good against one or the other..

> Now if you get a communications grade radio, some of my less tongue in
> cheek suggestions might help more. But make no mistake, you are deep

Apart from a few bits of ferrite and a coax, and a whip to get upwards reach
in a space where sidewards reach can't do much good, I'm not after much. I'm
pretty sure it will beat hanging the wire out the window of a house full of
modems and computers and other RFI generators.

Curious. If they were that worried about resistive losses, they'll be high on
the buyer list for room temperature superconductors if they think they'll
help.

I'm not complaining about the info. Already said I came here because I
thought the SNR was better. But there's also enough contradiction in advice
I've seen to suggest a considerable mismatch. So taking all of it is not only
unwise, but perhaps impossible.

They're about 2 and a half inches long, made of wax and look a little
like the nasty things we're joking about. Kids bite the top off, and
drink th esmall amount of flavored water in them.

I think I've seen something like them, though in some kind of clear pliable
plastic. Usually flat and flaccid by the time I see them in the streets.
Definitely unsavoury... I mean, they don't look exactly like a used condom,
but the older I get, the more I wonder about some of the stuff that kids find
fun to eat.

Hi OM,

Transformers further away have certainly lead to grief. It is
unlikely even at what you consider to be a short distance that you are
going to inject any problem into it during transmission. If you are
worried about that, then you really have to pay attention to the power
distribution inside the building that would be far closer.

If you are worried about noise being injected into your system by the
transformer; then survey the area around it with a portable HF
receiver (or VHF or UHF depending upon your band of operation will
be). Very simple.

This doesn't end it, however. The transformer can inject problems
into your system by your not practicing good grounding methods.
(Actually, the transformer will probably be benign in face of poor
ground handling that is beyond its role and responsibility.) That
alone is deserving of at least a string of follow up postings to this
thread.

Go to one of those library shelves that has a copy of the electrical
code and read it about grounding.

Dear KE5WZY:

You might find the electrical code in the library by itself or as part of
the National Fire Code.
Good luck. 73, Mac N8TT

Well firstly, adding an attenuator WILL degrade the Noise Figure of your
receiver.

Now whether this will have any significance depends on the original NF
of the receiver, and the level of External noise (atmospheric and man made).

It we take your 'ideal' set-up where you have eliminated the pick-up in
the building; you SNR will depend on the NF of the rx and the levels of
signal and received noise at the antenna.

So if we have to put an attenuator in line to make the rx happy so it
does not overload, then we will have degraded the rx's NF by the value
of the attenuator. So say a 10db attenuator will have degraded you NF by
10dB. It will also have degraded the level of input signal by 10dB, so
you have a double wammy.

Now the effect on your SNR will depend on which band you are listening
on ant the level of atmospheric noise compared to the NF of the rx. At
lower frequencies the effect will be less because the atmospheric noise
is greater and will swamp the rx NF to some degree. As you go up in
ferquency the NF will start to become dominant.

If we take the case of leaky coax and pick-up in the building, sure the
picked up noise will degrade the SNR, but the leakage is likely to be
very small in absolute level and adding any attenuation will take it
below the noise floor anyway. The differences in leakage between the
types of coax under discussion will be insignificant compared to the
attenuation values you will have to add to make the rx happy. That is
why I questioned the choice or rx, having to add attenuation negates the
need to have the ultimate in screening unless the pick-up is a very
high level (in which case you are stumped anyway).

Also if your building is that noisy then there will be significant noise
pick-up directly into the antenna which you can do nothing about. There
is a significant possibility that this will be much greater than any
direct leakage into the cable making such pick-up insignificant.

Perhaps you should tell us why you think there will be this pick-up and what you think the source is in the building. That will help you get a sensible answer.

One final point, you say "It's the separation of internal noise signals from external wanted signals that matters, same as for anyone using coax." I suspect that is about the last thing that most people think about when choosing coax, they normally think about the impedance first, then the transmission loss, size and cost. I doubt if the "the separation of internal noise signals from external wanted signals" crosses their minds at all!!

Jeff

Hi Jeff,

You will undoubtedly have two camps there. As for those expecting
>"the separation of internal noise signals from external wanted signals"
then they will be dissappointed or live happily with illusion; and the
others will, as you say, will select their transmission line (not
solely a coax) on the basis of those qualities they can expect it to
deliver.

The reason why I opened this up to include parallel line is that too
much superstitious quality has been attached to a shield. This has
been tangentially supported by measure of the cable transfer impedance
with the hope of using that to predict shielding efficiency. The
ordinary reader is left with the impression that by focusing on a
shield that the state of shielding is defined at the alter of the
coax. It is not.

"Cable transfer impedance" is measured in a highly defined manner with
an example of a very good graphic found at:
http://www.emcconsultinginc.com/docs/beldenTiAndSe.pdf

Replace the well grounded coax with a parallel line with its balanced
load and balanced source, and the transfer impedance for that system
will reveal shielding efficiencies easily equal to, or better than,
coaxial cables. That efficiency will vary by the degree to the
proximity of the parallel line to the ground plane, and its geometry.
This geometry is manageable with parallel lines, the coax has to live
with what it has.

Now, this counter argument is based upon the premise of the near
sighted quest for some goal that is achieved by the coaxial line alone
- in other words, a folly. However, what this counter argument does
is penetrate the balloon of complacency surrounding the investment of
superstitious qualities in successive layers of shielding. Without
care, those extra layers can inject MORE noise into the system than

that which exists in the environment. I have already written and supplied reference to that unfortunate side effect to no obvious comment about this paradox.

Thank you for you suggestion KB7QHC,

That seems the logical thing to do, is just try it out with some portable receiver, perhaps i can map the interference if any based on how many feet away. If I have to locate the tower somewhere else that might be what i have to do.

I had a very similar setup in Fl. Antenna mounted on a wooden light
pole net to a ground mounted transformer. No problems with it.

Hello, and if there's an interference problem it wouldn't be with the
transformer per se. What should be of concern is leaky/cracked MV
(12-14 kV) insulators (or higher voltages if you're near a substation).
Discharges around insulators spew both radiated and conducted noise
all over the MF and HF bands. Sincerely, and 73s from N4GG0,

Yes, that is what I am worried about, is RF leakage. I think probably
the best bet is to try out an antenna before permanantly erecting the
tower with a concrete base.

What kind of antenna system can I obtain retail, that would provide the
absolute best reception using only a 30 foot tower?

A friend gave me a forty foot Utility pole. Since I am not a climber I have not determined how to make the best of this in my continual antenna tinkering. I keep coming back to the hazer transit method. The device would be complicated by the fact that the pole is about 12 inches in diameter at the bottom and 6 inches at the top. I expect to bury 5 feet of it. I hope to construct the device so that there is NEVER a need to climb the pole. The galvanized wire rope on my Crank up mast that I purchased in the late 1970's is still looking fine.

Any experience or ideas are appreciated!

BTW, Any idea why this tram mechanism is called a "hazer?"

Hazer is a brand name of GlenMartin towers: http://www.glenmartin.com/catalog/page10.html,
maybe it was the guy that originally designed it, or it could have
just sounded neat to marketing.

what type of antennas are you planning on putting on the pole?
personally i would put a couple of good screw eyes with pulleys and
run some decent rope through them and use it for wires.

I think the word "Lift" is probably the most accurate term to use.
There is a good series on YouTube referring to "AntennaVater" for the
same type of device.

I want to keep the structure as general as possible so I can continue
to experiment with a broad range of Ham antennas from DC to light. I
shy away from rope because of the limited life expectancy.

Limited life expectancy????? I am still using some ropes I bought in
the 1960's. Some type of synthetic material nicely woven into a 3/8
inch rope. You need to investigate further, or buy some better class
of rope!

Hi

I'm building a Carolina Windom 80 Special. 66 feet long (25ft one side 41ft the other with a 4:1 balun at the off centre, 10ft coax down to a RF choke.

My question is. Can I use a FT200-2 RF Toroid wound with coax to make up a choke to use as the choke?

Thanks

agreed. for something not accessible like that you need decent uv
resistant dacron. that is readily available and lasts for many years
under load. Check it periodically for wear and pull replacements up
as needed without climbing. if the pole is going to have cables
running up to feedpoints then use wire rope, just be sure to use big
enough blocks with the right materials.

I made a mistake in the Toriod number. It is infact a T200-A.

I have found the answer I was looking for on a web site. See belowe. It
might help some one else with the same ideas of using this a choke.

My recommendation is to pick a different material. T-200-2 is a powered iron
material; the permeability is way too low to build an effective
coaxial-cable choke with. The AL value is 120 (meaning it takes 120 turns to
make a 100 uH choke).

You should be looking at ferrite, probably mix 31, 43, or 61. Mix 31
requires the fewest turns.

I have another question.

What is the T200-2 Toriod used for and why is it good for that purpose?

Thanks

Tuned circuits e.g. antenna matching & filters, that's about it !

#6 is even worse for HF broadband transformers

Too many folks use iron powder cores of all types for totally
unsuitable purposes.

UKM

Does any one know where I can purchase some Ferrite rings type 31 material
from in the UK?

and thanks to UKM.

UKM is right: iron powder material is not suitable for RF chokes.

Well done for finding out about Fair-Rite 31 material - you must have been reading Jim Brown K9YC's tutorials on www.audiosystemsgroup.com :-)

None of the UK amateur suppliers seems interested in stock large toroids or beads in this material (and believe me, I have tried) so the next best thing is to order from the USA.

As Jim Brown has often advised, order directly from an industrial supplier in the USA, and not one of the "amateur" suppliers. When ordering from outside the USA, the most cost-effective route is probably either Mouser or Farnell because they handle the international shipping and Customs clearance, so you don't get hit for the same one-off charges and 'collection fees' that a personal import would.

There is no import duty on these electronic parts, but of course you still have to pay 17.5% VAT on the whole bill.

The best value will depend on the size of your order, and of course on any special offers, but it's sure to be cheaper than any of the US amateur suppliers like Amidon. Mouser have a free Fedex shipping deal on orders above GBP50. Farnell can supply US stock from their Newark Electronics affiliate with an extra charge of GBP15 per order (they removed this charge for the whole of January, and maybe this offer might be repeated).

The Fair-Rite part number for the 2.40in #31 toroid is 2631803802. Paste this number into the search fields at http://gb.mouser.com and http://uk.farnell.com and search out the best deal.

Ah, too bad... Mouser currently have an 11 week lead time.

Farnell have 95 of them at Newark Electronics. (Ignore the wrong information about "43 shield beads". Farnell/Newark confirmed that the cores really are #31, but it may take some time to correct the web page.)

Also worth considering is the giant #31 clamp-on bead 0431177081... an exercise for the reader.

I only need about 3 of them I think, so the postage is a killer
unfortunately.

I have found some FT140-43's.

Do you know if I stacked 3 Ferrite FT140-43's rings and wound 6 winding of
RG58cu through, what would the maximum impedance Ohms could I expect @
3.5MHz?

Also how much impedance could I expect to gain every time I added another
FT140-43 ferrite onto the stack?

Thanks for you links and info.

Take a look at

http://www.karinya.net/g3txq/chokes/

http://audiosystemsgroup.com/RFI-Ham.pdf

http://www.yccc.org/Articles/W1HIS/CommonModeChokesW1HIS2006Apr06.pdf

Mouser and Newark are you only real options, watch out for special
shipping offers and take advantage of them when they occur.

The giant #31 clamp-on beads 0431177081 are expensive but equivalent to three 240 sized rings.

You need to double the number of beads each time to make a noticable
difference.

For worthwhile common mode suppression you need at least ten and
ideally eighty type 43 beads over a length of cable.

It's more cost effective to wind more turns. 2 x the turns 4 x the
inductance.

UKM

For the 4:1 Ruthroff balun Type 43 or 31 is not ideal for this purpose, use approx 12 bifilar turns on a FT240-61 core.

Wind the transformer with twin figure of eight speaker cable which is OK for low power up to about 100w. Use thin 100 ohm twin feeder sold by Spectrum Communications for higher power levels.

Hi OM,

Z varies by the square of turns THROUGH the center (turns are always integers, not fractions). Z is a function of formulation (the mix of the ferrite) which defines the optimum band(s) of operation. Z is also a function of mass, but it doesn't take much, a small bead that comfortably girdles RG58 will present several 10s of Ohms Z. Z is a function of frequency, but most ferrites exhibit very mild shifts in Z as frequency changes. You can chain beads or toroids to build up your Z. You typically want your choke at least 3X the Z of the feedpoint - 10X is very much more preferred.

As for resources and cost, go to your nearest computer monitor recycler and obtain any deflection coils that may still be around in this era of flat screens. They have been reportedly quite useful.

If you do this, you will have to characterize the formulation of the available ferrite through experimentation. If you have an antenna computerized analyzer, you can measure this directly. If not, this may take invention and thought (and more posts here).

We experience the same problem here in VK. Local resellers charge very high prices, and many US suppliers charge very high shipping on magnetics.

Another option is to look on Ebay, Ebay sellers who really want to sell internationally have reasonable prices... but be prepared for excessive shipping quotes from some.

>
> I have found some FT140-43's.

You could use these to make a common mode choke, but the physical size limits the amount of heat that they can dissipate and the power rating.

At low frequency, the impedance is close to proportional to the square of turns, and proportional to the number of cores stacked but for a core of this type, the inductor will probably be self resonant in the HF range and stacking cores increases self capacitance and reduces the self resonant frequency and the above approximation does not apply so well.

I should stress that self resonance isn't necessarily bad for these types of lossy inductors, you should put aside Rules of Thumb (ROT) that say to never use an inductor above its self resonant frequency.

I have written a short article entitled "A method for estimating the impedance of a ferrite cored toroidal inductor at RF" which you may find interesting, it is at http://vk1od.net/blog/?p=806 .

Is Neosid still selling product in the UK? I believe they stopped manufacture, but they may be selling product.

In answer to the shipping cost issue, I went looking for a locally available core that suited a general purpose HF common mode choke, and

Neoside produce a core larger than FT240 with a material that is a good choice for the purpose, similar to Fair-rite #52. I describe the design at http://vk1od.net/blog/?p=581 . Moving house has delayed completion of this, the design is done, the materials are here, I just have to construct one in a box and measure its common mode impedance to calibrate the amount of equivalent shunt capacitance. An alternative would be a stack of two FT240-52 cores.

Everybody, and every manufacturer has a recipe for common mode chokes, but if you do not provide a plot of common mode impedance, preferably R and X separately, then you might reasonably question the recipe.

None so more than the commercial purveyors of the magic Caronlina Windom which calls out aspects many of us might regard as a disadvantages as positive features (sheer marketing spin) and depends on undescribed proprietary components.

I did something like that a few years ago, to build a common-mode
choke for our ARES/RACES ham shack's HF feedline.

I used off-the-shelf (surplus-store) ferrite tubes - very probably a
43 mix or something close to it, based on the simple inductance
measurements I did with an MFJ analyzer. They're roughly 1 inch long,
and large enough to allow three through-the-center passes of RG-8X coax.

I glued somewhere around six of them, end-to-end, to create a long
tube, and then ran the RG-8X through... creating a long three-turn
choke. Added N connectors to the ends of the coax and stuffed the
whole thing into a chunk of PVC tube with end-caps.

The results were gratifying. When I tried a common-mode measurement -
along the braid, from one end connector to the other - the impedance
at 3.5 MHz was too high for the MFJ meter to read it... it simply said
"> 1500".

A normal (differential-mode) measurement through the coax, looking
into a 50-ohm dummy load, reads 50 ohms (1:1 SWR) as closely as
matters not (i.e. within the accuracy of the MFJ meter).

You're in luck, as I happen to have a few FT-140-43, and the measurement equipment is out on the bench.

That 3-core choke has its best performance around 15MHz (peaking at 4000 ohms, broadband and predominantly resistive, which is quite a good result) but at 3.5MHz it's only about 1900 ohms and mostly inductive.

>Also how much impedance could I expect to gain every time I added another
>FT140-43 ferrite onto the stack?

I had only one more to add, which moved the peak down to 12MHz, 5000 ohms, but only added a few hundred ohms at 3.5MHz.

Clearly these cores are not the best for your application.

I'm working on a better approach from the new ARRL 2010 handbook, which uses cores that *are* available in the UK and gives the best "value for ferrite" of anything I've seen. Publication is due in the May Radcom, but I may be able to give some previews in the next few weeks.

You might do better breaking the thing up into multiple cores and multiple windings. That is, rather than 3 turns through 6 cores, do 3 turns through 1 core, then 3 turns through another core, then 3 turns, etc.

The logic here is that the impedance scales as the number of cores, but doing them all in one shot means that the input coax is very close to the output coax, so you have a lot more capacitance coupling the input to the output.

I think Jim K9YC actually did some comparisons using #31 2.4" cores comparing stacking to stringing em out.

I will keep that in mind. I have about 250 feet of blue 3/8" Nylon
that was my primary anchor rope from my sail boating days. It has
served from time to time as a temporary guy line for ham radio.
However, to hoist the fixture a winch with a brake sounds more
convenient.

Hi guys, long time no see.

Well for various reasons I missed out on the last two solar peaks and with another one comin' down the pike not so very far away I'm determined not to miss out on that one, too. Trouble is, I'm several floors up in a metropolitan area. It's not as bad as New York, but nevertheless very far from ideal.

Any suggestions for an antenna type that's discreet (or at least not too outrageous) that gets out well at HF? Anything from 80m through 10m I'll take whatever I can get. I know given my geographical limitations I have to be realistic so I'm not looking at winning any contests or working DX every night. Just don't want to miss out entirely yet again. Any suggestions?

Got a outside facing window?
Balcony?

A 20 foot "black widow" collapsible fishing pole (try Cabelas online..
they run about $20 each, as of a couple years ago) can easily support a
pretty long wire hanging down away from the side of the building. You
have to think about the "other side" of the antenna, but another wire
serves there. If you have multiple windows, or some way to stick the
wire to the side of the building, you can make a sort of "limited
radials" scheme (think of a ground plane vertical turned on its side).

A tuner at the base of the antenna makes the mismatch issue go away, and
you can run the coax from the tuner to your rig. The SGC-239 is
convenient and works pretty well. (if you want to hop around bands or
within a band, having to reset a manual tuner each time gets old, real
fast, especially if the tuner is sitting on the windowsill or balcony
rail at the "feedpoint" and the rig is inside on the table where it's
more comfortable.

lay in a good pile of appropriate EMI suppression cores (I like the #31
mix from Fair-Rite, available in a variety of forms from Mouser and
Digikey, among others) so that you can deal with the inevitable RFI issues.

I have used something very similar to what Jim mentioned but literally
a collapsible fishing pole with wire tie-wrapped to it and another
dangling from the balcony rail. Matching was provided via MFJ tuner. I
found an antenna mount in the CB section of a truck stop that

consisted of a CB mount welded to a pair of locking pliers.

There's also things like a locking pliers (Vise-Grip) welded to a
C-clamp or pipe clamp (which looks like a C-clamp, except the fixed part
is a V shaped piece. There's also a clamp that is like a vise-grip,
except instead of jaws, it has a piece of bicycle chain and a hook. You
wrap the chain around whatever it is you want to clamp to, squeeze the
handle and it locks it in place.
http://www.irwin.com/irwin/consumer/jhtml/detail.jhtml?prodId=IrwinProd100322
http://www.irwin.com/irwin/consumer/jhtml/browse.jhtml?catId=IrwinCat100299

Take a look at a catalog for stage and theatrical rigging, grip or
gaffer's supplies. There's a wealth of nifty things to attach stuff to
poles/standards/posts, etc. They're always having to temporarily attach
stuff on a set or stage. Things like grip clamps with a baby pin are
useful.. For fun, take a look at the Matthews Meat Axe (pricey, but you
can hang remarkable stuff from it)

http://www.filmtools.com/gripclipandc.html
http://www.stage-n-studio.com/Cat_04_PDF_pages/Cat04-Light-Grid-1.pdf

If you want to get elaborate, look at stuff used to attach cameras to
cars and other stuff.

John, I think my ropes are dacron, as mentioned. That stuff really
lasts!!!! I still have two dacron sweaters my mother bought for me
when I started high school back in 1953. Still fit and have never worn
out. I haven't seen dacron ropes for a long time.

Sure, you've seen Dacron ropes, just not under that name. Dacron is a
trade name for a particular form of Polyethylene Terephthalte (PET), aka
Polyester. Beverage bottles are a big use of PET, but a lot more winds
up as fabric or rope. In film form, one trade name is Mylar.
(originally, it was called Terylene, but Dupont called it Dacron,
probably because it sounded better, and it was similar to Nylon, another
Dupont product..)

You see it labeled as "polyester" rope these days (probably because
DuPont's patents have expired, so anyone can make the stuff, but only
DuPont can call it Dacron)

The Glen Martin hazer looks like (I've never seen one in person) it uses the tower as a track, and the constant cross section is key. The taper of the utility pole sorta kills that idea, so maybe some kind of curtain track turned vertical is what you need, something industrial like the kind used in theaters. Bolt it straight to the pole and fabricate a trolley to carry a rotor, thrust bearing, etc. Once you get the trolley to the top wrap the cables around the pole in a spiral to keep them from flopping around in the wind. I'd use a galvanized wire rope as opposed to something plastic to pull and hold it up.

> BTW, Any idea why this tram mechanism is called a "hazer?"
> John Ferrell W8CCW

I have no idea at all, I thought it might have been something nautical but dictionary searches don't show that at all.

Hi all

I have been reading loads.

I have managed to borrow a Rigexpert AA-200. Is it possible to measure the impedance with a AA-200 analyser and how would I do that?

And a big thank you for all the links and info.

I don't have one of those particular analysers, but be VERY careful when measuring the high impedances that you'll typically see in RF chokes.

Most antenna analysers are primarily designed to measure impedances around 50 ohms, and they may be quite inaccurate for impedances of several k-ohms. Check with a 4.7k or 10k chip resistor... you may have a nasty surprise.

Also read Jim Brown's notes about the effects of the analyser's own shunt capacitance. Choke resonances in the HF region are the product of several uH of inductance but only a few pF of inter-winding capacitance, so a few pF of additional shunt capacitance from the analyser can make a big difference. The more advanced Vector Network Analysers have the facility to "calibrate out" such errors before making measurements, but the AA-200 doesn't seem to have that.

OK, thanks, guys. Antennas have always been my downfall. I'm afraid I am not very practical in that respect. I have read about some resourceful people running a wire around the edge of their living rooms under the carpet and working DX with 10W but I wouldn't feel comfortable with that. I believe antennas should be way up in the air away from other stuff. Stick a wire under your carpet just seems like taking a bath with your clothes on; there's something not right about it!

HI all,

A few questions have arisen in my mind since some guy came around to
install a wi-fi system at my girlfriend's apartment. This system uses
a dish and the signal frequency is 5Ghz. I asked the installer what
type of fancy, low-loss coax he was going to route the down feed with
and he told me "CAT 5" which I've never heard of. Anyway, it turns out
this stuff is essentially just telephone wire!
There must be some serious gaps in my understanding about transmission
lines, because on further enquriy it transpires the loss with this
wire is pretty low and the installer told me he can have a run of 100
meters before he has to worry about signal loss.
What's the deal here? How come I have to have some fancy, military
grad coax that costs a fortune and must be as short as possible just
for the 23cm band when this guy can use what is basically just phone
wire at 5Ghz and slop the stuff over half the building without a worry?

Would I be right in thinking that line loss in coaxial feeders is so
poor compared to open-wire/laddered feeders solely due to the
proximity of the conductors and leakage of current through the
dialectric? I mean, the capactive and inductive distributed elements
in a tx line can't disipate power so such loss can only come from the
distributed series and shunt ohmic properties of the line, and since
the *series* loss in coax and open-wire is going to be pretty similar,
the principal cause of coax being so lossy comes from current leakage
across the dialectric. Is that right?

Just need to get these things clarified!

The velocity factor of a tx line is governed by its distributed
inductance and capacitance, is it not?
I mean the more L and C you have per meter of line the lower the
signal velocity, right?
How much is the signal speed retarded by typically and are there any
circumstances where we need to be concerned about this phenomenon?

414. VNA coax recommendation

Newsgroup: rec.radio.amateur.antenna

HI,

I have an old HP network analyzer that goes up to 1.3Ghz. I need to make up some more cables for it, though, as the existing ones (not original) are far too thick and inflexible for comfort.

I have to cut three identical 2-foot lengths (for phase matching purposes) of some 50 ohm coax for this purpose, to connect the VNA to its bridge. Can anyone suggest a suitable, readily available coax for this job? The terminations will be N-types, by the way. I'd like something flexible and easy to terminate, ideally. Just don't want a cable that will change its Zo every time it gets a bit bent!

I believe there's a converter/demodulator at the feed point, so all that's being sent along the cat 5 cable is digital data at 100 MB/s or less. There's no reason you couldn't use cat 5 cable as transmission line up to 100 MHz or so, if you're willing to put up with the loss. It's specified as 24 dB/100 meters at 100 MHz, which is about twice (in dB) of the loss of RG-58. Loss of cat 5 cable would be extremely high, and it would likely radiate pretty badly, at 5 GHz.

Depends on the frequency. Below about 1 - 10 GHz, the primary loss mechanism in coax is conductor resistance. In that range, coax is more lossy mainly because of its lower impedance, resulting in higher current and consequently greater I^2 * R loss. At higher frequencies, dielectric loss becomes a factor but parallel wire lines become impractical because of the need for very close spacing to reduce radiation, along with problems terminating the ends of the lines.

Hi Barett,

Pass a single, short piece of wire through your core/bead. Connect it
to the analyzer. Read the Z. This will be enough to characterize
your ferrite material at any frequency within the range of the AA-200.
Now pass the wire (now longer) through your core/bead twice. Connect
it to the analyzer. Read the Z. You should observe four times the
earlier reading (you may have to perform complex math if the Z
contains substantial X).

Now pass the wire (now longer) through your core/bead three times.
Connect it to the analyzer. Read the Z. You should observe nine
times the earlier reading (you may have to perform complex math if the
Z contains substantial X).

Ferrite materials with one pass of wire will not exhibit a huge value
such as to lead to significant error, so as you progress through
successive passes of wire, you can be reasonably assured that the
square law will be observed within the capacity of the analyzer at low
HF frequencies (simply because the wire length being a significant
portion of a wavelength can confound measurements at higher
frequencies).

The single pass test will also help to select and compare previously
known and unknown ferrite materials.

The velocity factor for air dielectric cables is essentially unity. The slowest common velocity factor is about 0.66, which you'll find in coax (where the field is entirely in the dielectric) having solid polyethylene dielectric. Velocity factor is important in determining the physical length of cable needed to effect a specific time or phase delay.

You are way up in the air. The floor is merely an illusion of being
on the ground.

>Stick a wire under your carpet just seems like
>taking a bath with your clothes on; there's something not right about
>it!

Understandable, but it confuses the issue that you are already up in
the air. Rather, it is like taking a very high antenna, and draping a
carpet over it and nailing a floor under it. The building composition
will certainly have an effect. However, if you have heard of
>people running a wire around the edge of their living
>rooms under the carpet and working DX with 10W
then it would seem reasonable that their building composition is only
marginally affecting their antenna high in the air.

The only unknown that remains is how much YOUR building composition
will impact the same loop under a carpet. This is something that only
you can investigate. It couldn't take much effort to lay out the
antenna and listen to how much you can hear. That would go a great
distance in answering this unknown.

Possible, perhaps, but not practical. Assuming air insulation, the spacing between the wires would have to be just under 9% of the wire diameter, and this spacing would have to be maintained very closely to keep the impedance constant. I might still have some 72 ohm twinlead in my junk box, which consisted of wires embedded in molded polyethylene.

With your interest in transmission lines, you'd benefit a great deal from getting a copy of the _ARRL Antenna Book_.

Look up the velocity factor, a simple multiplier/divider of the
relative speed of light in a transmission line. This means that the
signal that hits your antenna will hit your radio over the air before
that same signal reaches it through the transmission line.

Your goals are at cross purposes. If the line is flexible, it is more
likely to change Zo than not.

Your analyzer should have a self-calibration feature (and you are
probably lacking the calibrated open, load, and short if you are
lacking the original leads). This will satisfy any arrangement of
leads once they have been laid out such that you don't have to move
them again. That in its own right should solve your variable Zo
(which is an unlikely problem).

A factor that you haven't considered is that the characteristic impedance of coax is typically much lower than open wire lines.

So, in a matched condition, coax usually operates at higher current and lower voltage, and for the same effective series resistance that you speak of, that would result in higher loss.

Under mismatch, the situation is different. You will see some graphs and formulas that purport to predict transmission line losses under mismatch, but the classic "Additional loss due to VSWR" methods depend on a bunch of underlying assumptions which are not usually stated and overlooked by most users.

You can learn from considering the following cases.

Which is lossier, a very short 300 ohm line or a 600 ohm air spaced line of the same length using the same conductors with a load of 10+j0 ohms? What about with a load of 10k+j0 ohms?

Such a low characteristic impedance requires very close spacing of round conductors. Proximity effect which causes the current to mainly flow in a small adjacent portion of the conductors at close spacing makes achivement of very low Zo at low loss very difficult, and not very practical.

TWLLC at http://www.vk1od.net/calc/tl/twllc.htm will perform the calculations for you, including calculating the matched line loss and loss under mismatch conditions, but read the comments on the page re proximity effect.

There is an interesting example.

K8ZOA published a characterisation of ZIP line some years ago in this groupd, and Zo is approximately 100 ohms.

Considering a half wave of ZIP cord with a load of 100+j0 at 14MHz, loss is around 1dB.

Now, using N7WS's characterisation of Wireman 551 ladder line, again a half wave at 14MHz, smaller conductors, wider spacing, longer, Zo=400, higher VSWR, the loss with a load of 100+j0 at 14MHz, loss is around 0.14dB.

it is also important when you try to get cables to reach a certain
distance and still be a given phase length. this is why foam coax is
specified for 1/4 wave lines feeding most 4-square vertical systems.
a solid dielectric line 1/4 wave long is too short to reach from the
center to the feedpoints.

It's possible to buy very nice, reasonably flexible instrumentation grade coaxial cables, but they are quite expensive. Hundreds of dollars each for a 1 meter long cable is not unheard of. In general, you don't want to bend your cables in too sharp a radius. That's asking for trouble with pretty much any cable. If you can arrange things so that you can install the cables and leave them alone, you'll stand probably the best chance of having a stable system. You might consider a bit longer cables if it lets you arrange them with larger radius bends. I'd go for cable like RG-213/U, or better, RG-214/U if you can find it. If you can get cable with solid Teflon dielectric, that will likely be a bit more stable. In any event, I'd certainly go for cable with solid dielectric, as foam dielectric lets the center conductor move around too much.

Is you analyzer an HP8754, with the transmission/reflection test set? If so, I understand exactly the issue you're dealing with. ;-)

Since you're only going to 1.3GHz, it's possible to build a quite respectable set of calibration standards from SMA connectors and 0.1% (or even 1%) 100-ohm 0805 SMT resistors. They'll serve quite nicely for pretty much any ham work I can think of. Icing on the cake is if you can get someone to measure them for you with a freshly calibrated precision network analyzer. I have built these sorts of loads using thru-hole SMA connectors intended for vertical mounting on a PC board. I cut the center pin off so practically none is showing above the Teflon insulator for an open, cut the center pin off to perhaps 0.01" and solder a pair of 100 ohm 0805 resistors from the pin to the shell, radially symmetric, for a 50 ohm load, and just add either a disc of thin copper (copper tape) or four radially symmetric wires, about AWG28, from the pin out to the shell, down flush against the Teflon insulator, for a short. I've made a few such 50-ohm loads and

find that it's practically trivial to get at least 40dB return loss out to 1.3GHz, which is better than I need for any ham work I've ever done. (Beware: "50 ohm" coaxial cable typically has a tolerance of +/- several ohms...)

Cheers,
Tom

>
> Thanks!

As hinted by others, especially Owen, it's quite possible to make parallel-conductor line of very low impedance. There are two ways that are easy to describe, and these may well bring others to your mind:

First, consider a line made of broad, flat conductors: copper ribbon. If the spacing is close compared with the conductor width, the impedance will be low. This is not particularly practical for "open-wire feeders," but is commonly used on printed circuit boards. In the extreme, you can make transmission lines with impedances under 10 ohms this way, if you're of a mind to. You can use thin, flexible Kapton tape, perhaps 0.1mm thick or less, and have conductors 10 or more mm wide. According to a formula in Sams' "Reference Data for Engineers," the impedance will be approximately 377*s/(sqrt(epsilon)*w), where w is the conductor width and s is the spacing. For air dielectric, where epsilon is 1, you can make a 10 ohm line if the width is about 38 times the spacing.

Second, consider a multi-wire line. One common construction is four wires arranged as in the corners of a square, with diagonally opposite wires connected together at the ends. That gets you a lower impedance than open wire with the same spacing as the side of the square and of course the same wire diameter...it's a bit more than half the impdeance. You could also have more wires arranged around a circle, with alternate wires fed in parallel. A variation on this theme has been used on occasion by rabid stereophiles to feed (~8ohm) speakers: use a 50-conductor ribbon cable. Mass-terminate with a standard two-row connector. Tie all the pins on each side of the mating connector together, so the transmission line is similar to 25 pairs that are fairly closely spaced. (IMO, there are better ways to accomplish flat frequency response in a stereo system...) But it does work to get a low impedance line. (And yes, if you look closely, you'll realize the transmission line impedance is NOT constant as you go to lower frequencies...)

On the other hand, there's generally not much advantage to making a low-impedance balanced line for RF work, so they are pretty uncommon in practice.

Cheers,
Tom

>
> Thanks!

Oh, and to more directly answer your question, the formula generally given for accurate description of the impedance of two parallel, round conductors of the same diameter, in air, is:

Zo = 120 * invcosh(D/d)

where D/d is the center-center distance and d is the conductor diameter. So...

D/d for 50 ohms = cosh(50/120) = 1.088

For 1" diameter wires, you'd have to space them 0.088 inches apart, which is tough to maintain unless you embed them in a solid dielectric.

I suspect the formula above is in error for very close spacings because of proximity effects...I suspect it assumes a uniform thin cylinder of current...but I'm not sure about that.

Cheers,
Tom

Something not mentioned by other replies I've seen: some transmission lines are made specifically to get delay. They are generally called delay lines. Typical construction is to use a helical coil for the center conductor, to increase inductance per unit length.

In straight TEM transmission line (typical coax), the propagation velocity is the same as the speed of light (or more properly of electromagnetic radiation of the same frequency) in the dielectric. For any dielectric I've seen used in transmission lines, that's just free-space speed of light times 1/(relative dielectric constant) of the dielectric. If the magnetic properties of the dielectric differ from those of a vacuum, you also have to consider that.

You need to consider velocity factor any time you're concerned with the phase shift of the signal propagating through the line: phasing lines for antennas, impedance measurements made by an instrument at one end of the line of the impedance of a load at the other end of the line, how long it takes a signal to propagate over the line, ...

Cheers,
Tom

And something else for you to ponder: Coax is generally available commercially at about 50 ohms and about 75 ohms, with a few lines at about 95 ohms and some specials of other low impedances. What would ~500 ohm coax look like (assuming a straight center conductor, not a helix)?

Cheers,
Tom

Jim's comment is a good one from another standpoint he didn't mention explicitly too: if you put a single choke right at the antenna feedpoint, and the feedline is in some sense resonant (e.g. a quarter-wave long with the far end grounded), the fields from the antenna may very well excite currents on the outside of the feedline anyway, even with a "perfect" choke. By putting the separate chokes spaced out along the line, say a quarter-wave apart at the highest operating frequency, you break up resonances that might otherwise occur in the line.

By the way, for a single-band choke on a band (10 meters) that was extremely troublesome for me in one installation many years ago, I wound (approx., from memory) 5 turns of the feedline coax into a solenoid coil about 12cm diameter, secured so they were stable. That made a coil of roughly 3 microhenries inductance, self-resonant just a bit above 30MHz. A pure 3uH would only be a little over 500 ohms reactance, but resonated with a wee bit of capacitance across the coil, the result was a very high impedance that solved the problem nicely. I've since found the technique valuable and easy to apply to RG-58C/U type line used at 147MHz--much smaller coils, secured on sections of PVC water pipe.

Cheers,
Tom

You see this in microstrip construction on various substrates,
particularly where it's part of a matching network for transistor
amplifiers (which can have Zs of a few ohms)

>

in RF communications, that's true.

In other high power RF applications, low Z can be desirable (because
you'd rather take the IR hit than deal with the high voltage).

In the pulsed nuclear research business you see lines with Z of a few
ohms in pulse forming networks :often using distilled water as the
dielectric.. that epsilon of 80 gets the C right up there so Sqrt(L/C)
is small.

I believe that standard fast ethernet (100Mbps) uses full duplex at
31.25 MHz with 4B5B encoding on top of MLT-3.

MLT-3 gives an effective rate of 4 bits per cycle, and 4B5B means you
need an extra 25% cycles. 100/4 -> 25. 25 * 1.25 for the 4B5B -> 31.25
MHz base frequency.

Yes, indeed a low impedance can be helpful sometimes...but the times I've been involved with low-Z lines, they've almost always been unbalanced (e.g. coaxial). For a PFN, the high epsilon is also an advantage in storing a lot of energy. Since even very pure water is pretty conductive (relative to seriously good dielectrics), I'm a bit surprised it's used. Are the cases you're thinking of balanced lines, or coaxial? Is the impedance also chosen to match the load (in some sense), or is there also a transformer at the output to match to a higher-impedance load?

It occurs to me that for a PFN, energy storage is a good thing...in fact, it's half of what a PFN is all about, the other half being delivering that energy in a controlled manner. But in power transmission, (excess) energy storage is generally a disadvantage. Lines with dielectric with high epsilon are lossier, and delay the signal more, than lines with low epsilon dielectric.

Cheers,
Tom

I think so, Tom. I can't be sure as it isn't within reach at present.
ISTR is was built in around 1978/9. It would be great to have it
working properly again. It has some fault in that it will only display
in one mode (It can't show polar/smith chart output for some reason.
However, I have all the service manuals and a ton of test gear and
whatnot so must get around to fixing it. Do you own one of these
beauties?

Both coaxial and parallel plate balanced.. For short pulses, the water
isn't all that conductive (because it takes time for the water
molecules to dissociate); you worry more about particulate or gas
bubble contaminants cause a dielectric breakdown.

For a spectacular example, look at the Z-machine.

An interesting read.

I think that if you had measured the loss, none of the options tried would be very attractive. Measuring a short stub with your new AIM4170 will allow calculation of the effective loss of the line.

I don't understand the detail of the connection neatness thing, but one way to construct a 50 ohm 'balanced line' line is with four 50 ohm coax lines. Cut equal lengths, tie all of the shields at each end together, tie pairs of inner conductors together, and use the now paired inner conductors as a 50 ohm 'balanced line'. Of course, the line is only balanced (in current terms) by virtue of its usage rather than its construction.

John, it will probably be easier [rather than redesigning either the pole, or a hazer] You can find plans for planting two sections of a powerpole, spaced slightly on each side of your pole. Those to be used as the 'base' for your pole to be sandwiched between. You want the base poles to be reasonably tall, to allow your's to be pulled to the vertical. You'll need substantial solid diameter rod, for your pole to pivot on. Don't forget to include a 'over-travel'
stop, and a means to secure your pole in place once swung up into vertical. There are photos of such antenna supports in Ham Radio references circa the 1930's and later. Remember you MUST periodically treat wood with anti-termite chemical. Approach your local telephone and/or electric companies for a source of pole material, and perhaps they'll even be able to place your base & swing-up section [for a fee ?]. All told, it might be more economical to buy a used tower in GOOD condition.

The one you want is from April 1964 Popular Electronics. There are many of
them here, but not the one you want.
http://home.gwi.net/~jdebell/pe/cj/cnjindex.htm

What they did was to wrap a plastic baby bottle full of water with a lot of
wire. Then it was hooked to a switch so a battery could be placed across
the coil for a second or so. Then it was switched to a high gain amp and

into the vertical channel of an oscilloscope. The horizontal channel was fed with an oscillator of around 2000 to 2500 Hz. The osicllator was adjusted so a circle was displayed on the scope. This was the self resonate frequency of the water molecules or whatever in the bottle. When the bottle was passed over an object the circle would spin or change indicating the frequency of the bottle had changed.
I must have been about 14 years old when I read this.

>condition.
Part of the problem here is that I failed to heed the old advice "Be
careful of what you wish for, you might get it!"

The pole was a gift from a friend in the construction business. I
never dreamed he would come up with it until one afternoon he showed
up with it at my house. I live in a rural setting with my house in a 3
acre field with trees down one side and across the back, a lane down
the other side. The house is set back 120 feet from the road. Being
zoned agriculture means pretty much free from regulation. I feel
obligated to at least make an effort to take advantage of these
circumstances...

Since I am now 70 years old, this thing does not have to last forever
and the pole seems to be nearly new condition now. As I see it at
this point, I intend to set the pole 5 feet in the ground far enough
from surrounding structures so that a fixture with a rotor platform
can be hoisted and stabilized into operating position with an electric
winch. I will endeavor to use as much as possible from my existing
stock of "junk" rather than accumulate more.

Perhaps what I learn & share will be of benefit to others in the
future if only as a bad idea.

Please keep the advice coming!

From link previously offered:
>The frequency at which the protons precess is directly proportional to the strength of the earth's magnetic field. This is the Proton Gyromagnetic Ratio, equal to .042576 Hertz / nanoTesla. For example, in an area with a field strength of 57,780 nT (such as my home), the frequency of precession would be approximately 2460 Hz.

If I am understanding the data associated with the device (bead) you suggested, correctly--"EMI/RFI Dï¿½mpare och ferriter Z=375 OHM @ 100 MHz", it would, indeed, take a number of them. Personally, I like to see a Z of 10 times that of the Z of the coax. For example, for 50 ohm coax, I would like to see a choke which would provide a "resistance" (Z) of 5,000 ohms to any rf currents which would be tempted to ride the braid(radiate.) While 10 of these devices may be sufficient (and would be affected\effected by the frequencies they would be used with); I would probably choose to use a few more.

If cost\design-needs is\are any sort of factor(s) in your design needs, I would tend to go multiple turns on a proper core size(power handling requirements of correct material(frequency(s) designed for.)

While ferrite may have advantages over iron cores at vhf\uhf\shf--and become quite noticible, I have found any losses or heating tolerable at hf and below--again, given proper core size\material--and I have used them at much higher freqs.

The beads you mentioned are very useful though. If in a hurry, if experimenting and time is valuable--just slap too many on the line and go for it! :)

Regards,
JS

Hi again,

Well I have read your informative replies on the problems with making a low Zo twin feed with much interest. Clearly it's not really a practical proposition. Shame.

So the obvious question is: why are transmitters normalised to 50 ohms when clearly 450 ohms would enable us to enjoy cheaper, do-it-yourself, lower loss feeders? Was this some oversight at the time, or good practice for some obscure reason that I simply cannot think of?

Twinlead transmission lines have to be kept away from other conductors, can't be taped to a tower leg, run through a metallic trough, or be buried. If there's a substantial amount of solid insulation between the conductors, it can get very lossy when wet. Even when properly balanced (often not easy to do), some field escapes so it can be subject to undesired radiation and signal pickup.

Coaxial cable has none of these limitations. It's a good trade for most people.

One story is that when radar was first developed coaxial feed lines were made by buying copper pipe at the local plumbing supply and the impedance resulting from using two standard sizes (one as the center conductor and one as the shield was 50 ohms.

A 450 ohm coaxial cable would be rather large.
Zo = 450 = 138 log(b/a) (where b=OD and a=ID)
For an inner conductor diameter of 1 mm, the outer shield diameter
would need to be 1800 mm or about 71 inches.

Well I've made 50 ohm line samplers (Bird 43 lookalikes) with standard
UK copper tee pipe fittings and pipe.

PVC pipe? Probably too heavy and too easy.

Maybe vinyl tubing or thin wall pipe. For stiffness, fill the tubing
with expanding foam urethane fence post compount, cement, or epoxy.

Perhaps an inflatable antenna using rolled vinyl tubing for the
structural elements? Just get a sheet of thin vinyl tubing, or heat
seal packing material, some glue, a hot wire sealing contrivance, and
build the quad.
<http://www.uline.com/BL_2107/4-Mil-Poly-Tubing>
The connecting wires will provide the required dimensional stability
(assuming they don't stretch under tension). Obviously, this would
not be a permanent installation. Something like this with a different
arrangement of supports:
<http://www.china-inflatable.com/products/sports/T11-364.htm>

Incidentally, there's no reason that the quad has to be square shaped.
The quad can be circular. A large round cardboard cylinder, with the
wire elements wrapped around the outside should work. Be sure to add
a tail so that it doubles as a wind vane.

You can also build an inflatable tower to support your quad:
<http://towers.ltaprojects.com/LTA_Towers/LTA_Tower_Home.html>

This solution for the formula also reveals the diminishing increase in
Zo for two-line or one line against earth as the separation grows
astronomically.

Let's put a 1mm wire 1000m in the air,
Zo = (138/e^.5) ï¿½ log(4h/d)
(138/1.667) ï¿½ log(4000/0.001)
82.8 ï¿½ log(4000000)
82.8 ï¿½ 6.6
546 Ohms

Tends to bend pretty easily under sidewise stress (including gravity).
Unless you fix the end of the spreader to the wire element so that the
wire takes up the bending stress, you'd find a PVC-based 20-meter quad
starting to sag badly quite quickly, I'd think.

Also, much standard PVC tubing doesn't stand up to sunlight very well.

>Maybe vinyl tubing or thin wall pipe. For stiffness, fill the tubing
>with expanding foam urethane fence post compount, cement, or epoxy.

I'd be concerned about the weight of the filling.

I've seen plans for PVC structures that have two different methods of
stiffening. One is to run fiberglass rope inside to a pair of eye
bolts. The threaded part of the eye bolts goes through a hole drilled
into the end caps. A nut at each end tightens the fiberglass rope.
Ordinary rope can be used but it tends to stretch and absorb water.
Once tightened, the PVC pipe is substantially more rigid.

Another method is to build a cross braced 3D structure. For a 2
element quad, that would be a box. Suitable end caps can be bought or
fabricated out of block of plastic (or a mess of PVC adapters).
Putting the box under tension between opposite end points should be
sufficient to provide structural stiffness.

>Also, much standard PVC tubing doesn't stand up to sunlight very well.

True. Per the advice of Dr Barry Ornitz, spraying the PVC with Krylon
acrylic clear plastic spray is sufficient to protect the PVC (and any
electrical tape wrapped around the connectors) from UV embrittlement.
However, the really good stuff has been recalled:
<http://www.cpsc.gov/cpscpub/prerel/prhtml09/09036.html>

>>Maybe vinyl tubing or thin wall pipe. For stiffness, fill the tubing
>>with expanding foam urethane fence post compount, cement, or epoxy.

Yes. I did one for a company doing exactly that at various
frequencies between 120 to 450Mhz. Sorry, but I don't have a copy of
the report. For convenience, we use ham frequencies for most of the
testing. What we found is that once a signal is reflected, the
reflected signals polarization is fairly random. There are few flat
plate reflectors in both man made and natural objects. The measured
result was a mess of varying polarization angles.

You can expect similar results for HF signals reflected off the
ionosphere with the added complexity of Faraday rotation.

However, it is beneficial to build polarization insensitive antennas.
In a common dipole, there's very little loss for polarization mismatch
until you get very close to perpendicular. There, the signal drops
off quickly. Filling in this hole is considered to be a good thing.

You can get a crude idea of how it works using an Adcock DF antenna
array, or just two cross polarized dipoles. Since you're not building
a direction finder, the crossed dipoles are easier to explain. Just
setup two perpendicular dipoles with the center feeds fairly close
together. Connect two well matched receivers to the two antennas.
Connect the IF or audio outputs to the vertical and horizontal of an
oscilloscope. The resulting Lissajous pattern will give you a rough
idea of the polarization (assuming the signal arrives from above).
Pick a strong steady signal like WWV. You'll probably see the
polarization change erratically when the skip is in. (Last time I did
this was 20 years ago). You'll also see that vertical and horizontal
parts of the Lissajous display to wander around in amplitude fairly
independently. This is the main advantage of a polarization
independent antenna. The antenna will automagically select the
strongest polarization to feed the receiver.

There are circularly polarized HF antennas, but I'm too lazy to Google
for them tonite.

I have a question about OCF dipoles; it refers to the choice of the type of balun transformer (voltage or current) to be used with that type of antenna:

Since an OCF has by nature an asymmetrical distribution of currents in its two legs, the use of a current balun seems a kind of 'brute force' imposing a symmetrization of the currents in the legs.

For the transformation of impedances, would it be more appropriate to use a voltage balun instead?

Thank you for that!
I have not seen the like printed any where soto me it is good stuff.
When I model a polarization independent antenna the individual gains
confuse me as each of the individual gains are some what 3 db down
from the "total" gain. In other words "total" is not the addition of
all the polarizations gains. I find it very difficult to get my mind
wrapped around that fact. On the surface it would suggest that
competition types would benefit from a polarization independent
antenna.

What is most important is the choking action which then demands a
current BalUn. As the transmission line falls away from an unbalanced
dipole, it also upsets they symettry further by its presence. This
further demands you choke it at quarter wave intervals away from the
feed point. As the OCF Dipole is meant to be multiband, this then
demands a number of such quarterwave-away chokes. My solution has
been to place a bead every foot along the entire drop.

The next trick is with the BalUn ratio. Few describe that accurately,
defend their choice, or even pretend to know. Further, the degree of
off-centeredness is another wild guess that none suggest makes a
difference.

Pierre,

An interesting question, especially in the light of some versions of OCF dipole that are attributed magic properties.

If you were to feed a half wave dipole in free space at the centre directly using a minute transmitter, the currents in the legs must be equal an opposite by Kirchoff's Current Law (KCL)... there are no other connections to the nodes, the tx is small wrt wavelength (deals with the standing wave issue), easy. It is an ideal antenna, not necessarily practical, but current distribution is ideal.

Now, if the development of the off resonance OCF dipole logic is to find a feedpoint with a more suitable Z, then feeding it with the same physically small tx would give the same 'ideal' performance. No matter how you achieve it, the objective is equal but opposite currents each side of the feedpoint.

However, as you know, using a remote tx with feedline doesn't compare with the above ideal case. It is very challenging to reduce common mode feedline current to the point that it is insignificant on all frequencies, even with one or more current baluns.

So, if you want to market such an antenna, how do you deal with the nay-sayers?

You get creative. Don't hide the disadvantage, call the effect out as a positive feature. Yes, feedline radiation (in the right place) is one of the advantages! There, that has neutralised the nay-sayers, and 'enlightened' buyers will go beyond conventional thinking and embrace this new concept.

Now, how do you maximise this fill-in vertical radiation? Use a voltage balun and explain it to people using DC circuit theory that the voltage balun (extremely low common mode impedance) will not impede common mode current flow at this all important circuit node.

Ah, but now you will have the dreaded 'RF-in-the-shack syndrome'. Ok, lets fix that with a magic component, an 'isolator' that is explained again using DC circuit theory as a switch, that blocks the common mode current at the bottom of the designate vertical radiator. Of course, this explanation is not consistent with KCL.

Brilliant! No wonder the Carolina Windom is so popular. With the trend to 'rebalance' the amateur population from a bunch of self taught OFs with knowlege related to experience and age with infusion of a growing proportion of six hour hams, the Carolina Windom's future is assured. A solution to the ham's quest for the Holy Grail, a low cost antenna for all HF bands with most importantly good VSWR, no need for a lossy tuner.

It was explained to me by many people as we created our structure for six hour hams that modern hams have no need for circuit theory. I counter with the example that a common component of HF stations is a simple device with three passive components, two capacitors and an inductor, and it is capable of consuming the majority of a tranmitter's output power when used without appropriate knowledge, and it is not well understood. Yes, it is the humble T-Match ATU. If you are interested, have a look at my article "Is a 4:1 balun a good choice for use with an ATU on HF?" at http://vk1od.net/blog/?p=987 . There are a bunch of recent articles in the blog on ATU and feedline matters that might prompt thinking about traditional ATU designs and advice on feedlines and balun types and ratios.

I am unusally sarcastic this morning, but the above is not really written in humour, and not really a lament.

A current balun at the feedpoint will not of itself reliably eliminate common mode current on the OCF feedline, nor will an 'isolator' of itself at another point reliably eliminate common mode current in the shack.

The same can be said for the same components in a symmetric centre fed dipole system, just that the common mode current is (much?) lower by virtue of antenna symmetry.

Owen

475. Re: OCF: Proprer type of balun (transformer)

Newsgroup: rec.radio.amateur.antenna
Date: 2010-02-15 20:11:09 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <wcudnakvb6H9N-TWnZ2dnUVZ_gmdnZ2d@giganews.com>
Source record: 10975

Richard made a good summary about the problem with common mode currents. I'm a little leery, however, of the suggestion of putting a bead every foot. The reason is that a common mode choke (aka current balun, or bead) has low loss if its impedance is either much higher or much lower than the common mode impedance. Loss is maximized when it's roughly the same. So I can see situations where the distributed beads might end up dissipating a significant fraction of the applied power. But I've never set up and measured such a system, or modeled one, so don't have any evidence this would happen.

As the developer and seller of antenna modeling software, I also caution people that models of the types of baluns and transformers commonly used for OCF dipoles are greatly in error when used as an OCF feed. The problem is that on many bands the transformer or balun is operating with impedances well outside its design range, and consequently adds series and shunt impedance and exhibits a changed transformation ratio.

Here are a couple of postings I made on this forum some time ago:

3/10/07

Here are some characteristics of off-center fed dipoles which I've observed in doing careful measurements:

1. The feepoint balun is commonly a voltage balun, which may have the nominal claimed impedance transformation ratio over most of the HF range when terminated with 50 + j0 ohms times the tranformation ratio. However, the antenna doesn't have this impedance at hardly any frequency, and can be very different at some frequencies. When presented with load impedances typical of the antenna, the transformation ratio is way off and becomes complex, and the balun adds considerable shunt and series reactance.

2. Whenever a voltage balun is used to feed an asymmetrical antenna, it creates an imbalance current in its attempt to equalize the voltages at the two halves relative to the "cold" side of the input. This imbalance current flows down the feedline as a common mode current.

3. Additional common mode current results from the unequal mutual coupling between the feedline and unequal antenna halves.

4. It takes very concentrated efforts to reduce the common mode current to a low level on all bands. Multiple current baluns (probably what the CW calls and "isolator") are required, and even then it might also require feedline length adjustments to get low common mode current on all bands.

5. Without being able to quantify what the feedpoint balun will do in terms of transformation, reactance, and common mode current generation, it's impossible to build a model of one of these antennas with any confidence, even if the feedline is included in the model. The best efforts I made to measure a real antenna and its balun and build a model based on the measurements led to generally poor agreement between the measured and model impedance. Consequently I'm extremely skeptical of any model that purports to predict anything about OCF dipole performance.

9/22/08

A while back I did some pretty careful measurements of an OCF dipole. I found that ferrites were required at both the feedpoint and at one or more places along the feedline. The ferrites at the feedpoint suppress the conducted common mode current (which is actually forced to exist by the voltage balun). But the asymmetry of the antenna results in common mode current being induced onto the feedline by mutual coupling to the antenna. This isn't a problem in a symmetrical dipole if the feedline is positioned symmetrically relative to the antenna, since the currents induced by the two equal halves cancel. But the OCF dipole can result in quite a lot of induced common mode current.

Ideally, you'd put at least a second bunch of snap on cores about a quarter wavelength from the feedpoint. But one of the main reasons people use OCFs is for multi-band operation. So the thing to do is to place the cores for maximum effectiveness on the band(s) where you have the most trouble -- the common mode current also depends on the feedline length and position, and will vary considerably from band to band even if you do nothing.

My opinion is that users of OCF dipoles are just about always going to have to deal with some amount of common mode current, and the best you can do is reduce it to a level you can tolerate.

Hi Owen,

Maintaining your DC analogy (argumentum), the isolator (if, indeed, we mean isolation of CM from the shack) can be achieved if the drop line's coaxial shield at the bottom end is immediately driven into an RF ground, AND the line routed on or beneath ground to the shack (where it can emerge from ground for normal considerations of terminating to the rig).

Routing the transmission line (coaxial cable) in close proximity to ground alone (no separate connection to ground) for a sufficient distance could easily eliminate common mode RF from the shack.

Thus, we would have a tripole antenna with three off-centers. The vertical element would be grounded at the end and would present a wealth of marketing opportunities. It wouldn't necessarily be a bad antenna (performance-wise), but the design variables could eliminate a significant population of customers.

I've always wondered, when people take these antennas that are likely to have feedline radiation, and try as they may to stop it, isn't it likely that they are making the antenna not work as well as it might have if we just left the feedline radiate as it would? You might be taking away a major part of the antenna performance?

I have to expect that a radiating feedline would have to be a pretty inconsistent sort of antenna from one installation to another.

Richard, are you sure you didn't serve an apprenticeship in the marketing department?

So could you calculate the advantage as 20log(tripole/dipole), or is it just 10log(tripole/dipole)? Maybe the FCC's bodgy 40*log?

The common mode path to dirt helps to tame VSWR excursions, between that and a lossy voltage balun at the feedpoint, you might keep VSWR under 1.5. And a bodged interpretation of Mismatch Loss could let the seller claim, VSWR<1.5, no expensive lossy tuner, MismatchLoss<0.2dB.

From time to time I lift my head, blink a few times, and utter some banalities, so here we go.

The OCF topic got me to thinking, what is a Zepp?

I may even have the wrong terminoligy, I'm speaking of the antenna fed with ladder or open line, and one end of the line is fed to the antenna, and the other just sets up there, lonely and tied to nothing.

Is this the ultimate waaayyy off center dipole? I'm assuming the feedline radiates a LOT.

Hi Mike,

For one, as we understand a Zepp, it is very long in relation to
wavelength. This means at some frequency it is a Hi Z resonance we
are feeding and hence a very small current. As current is generally
regarded as the indicator of radiation, any pigtail (that portion of
the remaining off-center) would barely contribute at all.

However, for what we understand to be a Zepp, there is no pigtail;
except, perhaps, the transmitter itself as the Zepp is classically fed
from the antenna connector (or the plate tank). This, of course,
gives rise to RF being in the shack and all the concomittant problems
that follow from that. (How in the world did they ever come to this
design in a hydrogen filled balloon? Such is the anachronism of
naming conventions, actual dimensions, history, and the Hindenburg.)

To return to your question, yes, the Zepp is the degenerate form of an
OCF dipole.

It's part of Polarity Therapy:
<http://en.wikipedia.org/wiki/Polarity_therapy>
I think it has something to do with yin and yang polarization.
Applying acupuncture to the coax cable is known to activate and
improve the flow of Chi, as well as increase the life force energy,
which is what produces the necessary gain.

(Sorry, I couldn't resist).

Hi Jimmie,

EZNEC, for one, reports antenna "gain"/directivity (re dBi) for each
polarization, azimuthum or elevation; or their sum as a total field
for a 3D model.

When two antennas (one receive, one transmit) are cross polarized, the
gain between them can vanish to zero. In a real application this zero
is something larger, but still small like 30dB down compared to two
antennas employing the same polarization.

This last is observed in line of sight transmissions of VHF and above
(try hitting your favorite 2M repeater with the wrong antenna
polarization orientation). It is not so common at HF as long paths
(aka skip) can blur the polarization (as can nearby reflectors for any
frequency) causing intermittant fading.

Apparently Art believes that a radiated, linearly-polarized a-c
waveform has a unique polarity, rather than a unique polarization.

If you use a circularly polarized antenna, and feed it a linearly
polarized signal (either vertical or horizontal) you'll see a -3dB
polarization mismatch loss.
<http://www.antenna-theory.com/basics/antennapol.php>

>I find it very difficult to get my mind

Nope. According to my friends that do contesting, the major
requirement of an antenna is NOT to maximize the gain in all
directions. It's to reduce the gain to the side and back, where all
the other interfering stations are usually located. Directionality is
important or all you're going to hear are other local hams. A truely
isotropic antenna is fairly useless for contesting. (Note: I don't
do contesting).

> - 73 de Mike N3LI -

Absolutely. A radiating feedline is part of the antenna, as is the entire path to the Earth along the outside of the rig, through the mains power system or whatever other path it can take. So two people thinking they have the same "antenna" can really have very different radiating systems.

Sometimes the radiation from the feedline, mains wiring, and stuff in the shack can be beneficial -- it might, for instance, fill in deep nulls in the main antenna's pattern and result in a spectacular signal strength improvement in particular directions. On the other hand, it can cause lots of problems. For example, when I was testing an OCF dipole a while back, on one band my electronic keyer would lock up after the first "dit" due to RF in the shack and on all the station connecting wires. And having the power wiring be part of your antenna system can lead to trouble with telephone, TV, and other kinds of interference. But then you might get lucky and get away with it.

Probably because of the same personality quirk that led me to become an engineer, I prefer to be able to predict and understand how my antenna system will work, and design it to work as I want, rather than making it a crap shoot. But that's surely not the only, or necessarily the best, way to get on the air and talk to people.

> - 73 de Mike N3LI -

Yep, you've got it right.

Here's a way to understand why the Zepp feedline *has* to radiate. If the feedline didn't radiate, it would mean that the currents on the two conductors were equal and opposite. At the antenna end, one conductor is open so no current flows from it. If the currents were equal and opposite, there would be no current flowing from the other conductor to the antenna. And if the antenna had zero current, it wouldn't radiate. So if the feedline didn't radiate, neither would the antenna.

In fact, the radiating and non-symmetrically placed feedline also couples into the antenna, altering its current flow somewhat.

The Zepp antenna is so named because it was allegedly used in the form of an end fed trailing wire on Zeppelin airships.

To be honest Jeff the antennas I design are based on starting with a full wavelength radiators which I presume you are already aware of. Initially I was basing efficiency on all forces being accounted for with a higher gain resulting. In fact this aproach to design provides diversity of polarizations instead of linear thus linear seamed to supply top gains.
The full wave length aproach gives the option of dual polarity or even all forms.
The penalty is usually in the 1db range where as the multiple polarity may drop down a bit on gain but makes use of signals that a linear design cannot hear as well as zero side lobes and good front to rear figures. So without knowing what polarizations one has to deal with a reasonable choice is hard to come by. On top of these questions one has to look t what "gain" really represents since cross polarization can be reduced to just noise with the rest of the db gain value representing quality signal. Thus it is difficult to quantify gain when the real advantage comes about on weak signals that others cannot hear. In other words gain itself is not important unless it is a measure of discernabilitity or quality above
noise or none matching polarities.
Two antenna designs come to mind 1 is the two element array that can supply 2 polarities,
horizontal and one direction circular and 2 the helical that can accept all that is thrown at it
with a prime gain around 13 db and 10 db for the others. Thus if polarizations are random
with weather fluctuations in city or wooded area it would seam reasonable to discard linear forms in favour of helicals. To sum up, all the above has placed me on a zero level as to what antenna efficiency really means which to the reader must now be obvious, as one does not know what variables should be weighted and by how much.,

No, the phenomenon I'm talking about is feedline radiation, which is very difficult to prevent with a non-symmetrical antenna like an OCF dipole because of their asymmetry. It has nothing to do with resonance or non-resonance, or wideband or narrowband characteristics. You can, of course, cause feedlines of symmetrical antennas to radiate by imbalanced feeding. But this is as true of a resonant dipole as a random length symmetrical antenna.

Different? How? All pretty standard stuff.

As for different literal perspectives of polarization, I am sitting here with two sets of 3D glasses for "Avatar" (just got back from the IMAX version) and these two pair of glasses are very different from my experience with Polaroid lenses of days gone by. And they are very different from each other for the same movie.

The Real3D glasses at IMAX didn't work as normally worn, I still saw a double image; but viewing the movie through the lenses backwards (ear pieces going forward) rendered the IMAX 3D as 2D.

Now, when I sit here at the console and view the display (flat screen) through the IMAX lenses, I can dim the display by rotating the pair. One eye piece goes black at 45 degrees rotation, and the other eye piece goes black at -45 degrees rotation. Flip them to look through them backwards, and the same effect is observed.

When I take the Real3D pair and rotate them, only a slight shift in hue: yellow tint in both lenses at 45 degrees rotation, and a blue tint at -45 degrees rotation. When I flip them to look through them backwards, I encounter a slight brightening for both lenses at 45 degrees rotation and a complete blocking for both lenses at -45 degrees.

I am familiar with display technology employing LCDs with double polarization to increase contrast, and I could easily expect this from the lenses of these two pairs of 3D glasses. Without having gone further into researching it, I have a hunch that I am encountering circular polarization here.

A little digging will tell.

When I listen to the local 2m beacon (horizontal polarisation) which
is north of me ,I get a strong reflection from something to the south
that turns the polarisation vertical. I noticed that while testing an
antenna in the garden.

Whether or not you account for all forces will not have any
effect on gain. :/
This is another case of the hopeful free lunch..
But the cupboard was bare. :(
The radiation from the vertical and horizontal polarizations
added together will never end up being more than you started
with.
And an antenna that is a mix of both will be a compromise
if the other antenna is purely one way or the other assuming
no reflections, etc skewing the path.
No free lunch.. :(

I am slightly OT here, but the same argumentation could be used about non-resonant antennas like the G5RV. Yes, ATU needed, but L-type autotuners for example have very small insertion loss.

I am wondering about the real advantage of a razor cut dipole (resonant anyway on a small region around a freq) versus a multi-band dipole using a length of feed line matching section like the G5RV or ZS6BKW/G0GSF Antenna System...

As far as I know, the key advantage of a resonant half-wave dipole is that its feedpoint impedance is a pure resistance, and generally low enough to provide a decent match to a coaxial feedline. The radiation pattern of a dipole changes very little with fairly large changes in frequency, until it becomes somewhat longer than one wavelength. Even then, it doesn't become inefficient; it just develops lots of lobes and nulls as its length in wavelengths increases (which may or may not be a disadvantage). Reading between the lines of what Roy wrote, a bit of feedline radiation will at least change where those lobes and nulls are. But even a relatively short antenna (e.g. a dipole that's only 0.1 wavelength long) can be quite efficient--the loss is typically mainly in the network (including the feedline) used to feed power to it. Another factor to consider for electrically short antenna is that you have to tune out a reactance that's large compared with the radiation resistance, and that makes them narrow-band if the matching network is efficient. You have to re-tune for even small changes in frequency.

Cheers,
Tom

Historically, a Zepp has been defined as a 1/2WL wire end-fed with 1/4WL of parallel feedline, a single-band antenna. MFJ sells such HF antennas modified for 50 ohm feed. The 1/2WL end-fed wire has a very high feedpoint impedance thus minimizing the current at the feedpoint and minimizing the absolute magnitude of imbalance (but not the percentage of imbalance). For instance, the current for 100 watts into a 5000 ohm feedpoint impedance is 141 ma., a magnitude less than the 1.41 amps into 50 ohms for the same 100 watts. Seems to me, the low current at the feedpoint, which can be considered to be common-mode, ensures a current minimum for both differential and common-mode standing waves.

P.S. A Double Zepp is the same thing as a 1WL center-fed dipole.

Something that hasn't been mentioned is that common-mode energy forms into standing waves, e.g. on the outside braid of the coax. An isolator (choke), as exists on a Carolina Windom, may only change that point to a current minimum while simply moving the current maximum point to a different location. Has anyone actually measured the common-mode current on a Carolina Windom on all bands up and down the coax on the shack side of the isolator?

Which makes perfect sense, since it means that if you tilt your head,
you don't swap images between left and right eyes. A very clever use of CP.

Other references exist, but you probably want to take a look at
Scientific American, "The Amateur Scientist", "How to make a sensitive
magnetometer" February 1968, page 124. Used discrete transistors and LC
filters on pot cores. I suspect one can do much better today with opamps
and microcontrollers, and I'm sure someone has done it if you google around.

A lot of the temporary job-site companies (e.g. Andy Gump, here in Southern California) that supply restrooms, power, etc. can plant a pole for you.

Cable TV companies plant a fair number of poles, but almost universally hire contractors to do it, so what you'd need to do is find the contractor. Watch for their trucks.

re: "ensures a current minimum for both differential and common-mode
standing waves..."

I don't think it guarantees it. Consider the case of end-feeding a
"fat" half-wave-resonant antenna, like a cage or what I recall used to
be called a "flat-top" with several wires running parallel in the same
horizontal plane, connected together at the feed end (at least).
Consider feeding it with high impedance (600 ohm) open wire line. The
data I have suggests it's possible to have a feed line impedance
higher than the feed-point impedance of the end-fed half-wave (fed
against the counterpoise represented by the feeder). In that case,
the differential load impedance at the end of the feed line (the feed-
point impedance of the antenna) is lower than the feed line
differential impedance, and we must be at a maximum current point on
the feed line.

Admittedly, it's not a case you'd run into very often, but it appears
to me to be quite possible.

Cheers,
Tom

That is the issue with the Zepp. Radiation is the result of current flowing in the 'flat top' and the common mode component of current flowing in the not-standardised feed line.

If the feedline was say a quarter wave vertical section (as is often depicted) with the common mode point at the bottom effectively grounded (not usually clearly described), you have a three quarter wave L fed one quarter wave from the end. If the common mode point referred to above was effectively isolated from ground, you have a different antenna, different boundary conditions to satisfy. Still, the are all Zepps to us!

Owen

I would never use a relay to switch from polarizing current to detection mode on the sensor\coil ... even a simple two transistor flip-flop would be immensely preferable.

Exactly. People tend to look at the flat top as the "antenna" and the twinlead as the "feedline". In actuality, the "feedline" is an essential part of the antenna, and any changes in it modify the radiation characteristics as well as the impedance. The same binary thinking often misleadingly separates "antenna" from "ground".

You're right, Tom. I was assuming an end-fed 1/2WL "thin wire"
configuration. Here's a question for the experts. If the current at
the feedpoint is 140 ma into the 5000 ohm 1/2WL wire and zero on the
other (open) wire at the feedpoint, what are the currents in each wire
1/4WL back down the feedline at a 1:1 choke-balun, for instance? What
would those currents be when fed from a link coupling not referenced
to ground?

Nice info how to use the AA-200. Thanks

I read on the internet while reading through all the links that I should
make sure when ordering the 2631803802 #31 that they have been coated with a
hardener. Because a ferrite ring #31 that has not been treated with hardener
will break easily because the material will be too brittle.

I have been in touch with http://gb.mouser.com and http://uk.farnell.com and they both say that there Fair-rite ring 2631803802 #31 does not come treated with any hardener.

How important is it that they should be treated with hardener and if not treated how easy are they to break?

Don't worry about it. All ferrites are hard, brittle ceramics, but quite rugged and not easily broken. They're already harder than most steels, so I don't really believe they're ever coated with a "hardener". I've seen them coated with an epoxy type material, but assume that's to make them less porous and abrasive. It doesn't make them any easier to break.

Yes indeed.. they're hard and brittle.. Drop one of those 2.4" toroids
off a ladder onto a concrete floor, and they break.

But other than that, they appear to be pretty tough. The ones I've
gotten don't have any mold flash or lines and are smooth surfaced.

That article is dated "February 06, 2007 (8:00:00 AM)" so it's not
exactly breaking news.

Fldigi is currently at version 3.12.5, available via
<http://www.w1hkj.com/Fldigi.html>

So, what exactly is "amuzing" [sic]?

1) Written by yet another asshole who doesn't understand that "ham" is a
derrogatory term.
2) Nothing in that article is anything new, as compared to the 1990's, as
far as digital operation goes.

Ham is a "derrogatory" term?

You can't spell, or run a spell check. And apparently you haven't a
clue which would indicate you aren't a ham either.

There is even a complete linux live CD based on the puppy distro that has fldigi and a host of other ham software "out of the box"

There's a blog on it here
http://w3dbj.blogspot.com/2009/03/re-using-old-computer-hardware-for.html

Well, to give D. Stussy some credit, it's true that "ham" did start out as a derogatory term. It was used by some commercial (ship?) radio operators, back in the Olde Days, to refer to some early high-ego amateur operators who were cluttering up the airwaves with their spark-gap transmissions (long since outlawed).

The term has long since been absorbed by most of the amateur radio community as a self-deprecating term of identity and pride. It's certainly possible that some of the licensed amateur operators I know would take offense at being referred to as "a ham", but I can't recall ever hearing anyone object to it. I certainly don't mind. In fact I think it's a good thing when somebody looks at my car's license plate and says "Oh, you must be a ham!" - it says that a member of the public is at least aware of us. If the term isn't meant in an offensive way, why take offense at it?

I think the modern linguistic equivalent to the original derogatory meaning of the term would be "a lid"... and this is *not* something I would ever hope to be called with justice!

There's no requirement to run a "speling-chek" on any Usenet article.

Ham: Correct - I'm NOT a "ham." I'm a licensed amateur radio operator.

In addition to the historical meaning recognized by another response,
there's another relevent meaning: Have you noticed that many operators are
not only overweight but actually obese. Maybe they are "hams" - they
certainly are pigs! Their fat proves such.
```

Or, put two of them loose and with not protection in the post.

Actually, the easiest way I have found to chip them is to thread them on coax for a W2DU balun, and let them fall just a couple of inches (hang on, we are metric, that would be 50.8mm).

Here we go again. I'd rather be super fat than be an ignnorant fellow
that thinks that weight is a metric of worth.

And seriously, if you have such a problem with being called a Ham, there
are classes and counseling available to improve your "self worth" image.

Then you might not be so touchy or feel the need to denigrate the obese.

I'm a ham.

I do public service.

I have elmer'd 6 new hams so far. And I expect to do more.

I've done hundreds of hours of public service.

I've done work which enhanced the art, at least a little.

What does weight have to do with anything I mentioned? What would it
have to do with those "hams" that showed up by the dozens ON SITE during
Katrina?

Dear Group:

Words often communicate different things to different people - perhaps
because of their background. I would never describe a licensed radio
amateur as a "ham" unless his/her behavior justified that tag.

Obviously, each reader has a different background and thus their reaction to
the use of "ham" is expected to be different. Let us not reject outright
the interpretation of others just because their interpretation is different.

I have commercial licenses, have quite a bit of education, experience
and make my living in various aspects of radio, should I be offended
when referred to as an 'amateur'?

> Obviously, each reader has a different background and thus their reaction to
> the use of "ham" is expected to be different.

Context is a clue but comprehension is the responsibility of the reader.
If offense is taken but not intended whose problem should that be?

> Let us not reject outright
> the interpretation of others just because their interpretation is different.

That goes for the writer as well as the reader.

My advice: Start with context and comprehension, because there are more
worthy things to get upset about.

Of all the groups I interact with the radio crowd is the last I'd ever
thought would get all Politically Correct.

> good practice for some obscure reason that I simply cannot think of?

The RG8 (and RG58 RG6 RG 56) standards were developed during WW2 as US military standards.
The RG8 52 OHM feedline standard goes back to the original RG8 MIL SPEC, which has long since been abandoned.

The demand for COAX cable during the early days of WW2 FAR outstripped the existing manufacturing capacity.

RG8, given the existing constraints on the amount and type of available matierials available and the volume needed; was deemed the most economical and easiest to produce.

HENCE RG8's impedance (52 ohms) became the standard.

Many RF devices outputs and and RF connectors were harmonised to work easily with RG8 cables.

Several factors have led to 52 ohms CONTINUING IN USE FOR ALL THESE YEARS:

1)Because of the large installed base of RF devices, after WW2 52 ohms became the de facto standard.
2) large numbers of RG8 compatible connectors and accessories are available.
3) RG8 cable does not "leak" RF like 450 open ladder feedlines, consequently,several cables of the RG8 family can be run physically close to reach other without encountering cross talk problems.
4) RG8 cable is easier the thread through contricted spaces like bulkheads and walls.
5) RG8 is physically more rubust than 450 ohm ladder line

Trying to improve my reception from Chicago with baseball season approaching. I'm about 100 miles sse in Indiana. I ran about 75' RG-6 from my radio across the attic and outdoors to a tree. I had maybe 10 extra feet of coax so I wrapped it around the tree. I strung about 50' of #9 steel wire between 2 trees going east/west about 15' above ground and attached the copper conductor to it. I terminated the coax shield at the tree with a ground rod. At the radio I attached the shield to the ground terminal and the center cu conductor to the other am external antenna terminal.
It greatly improved my reception I get all the major Chicago sports channels, but the one I was most interested in 670 is the worst. What all did I do wrong and what can I do to improve 670?

When I was a kid I tried to pick up a 50Kwatt station that was about
100 miles away. I lliked the station because it always played the
music I liked while none of the local stations did. If I was 30 miles
south or east of my location I could pick it up fine on the car radio.
No antenna I tried worked reliably from my home. It was just too far
away.

Dear Jeff D (no call sign):

WSCR 670 kHz appears to be sports station - as you suggested. It streams audio on the internet at:
http://radiotime.com/station/s_22732/670_The_Score.aspx

It is a 50 kW station with a nondirectional antenna. I had thought that it might have a dip in your direction, which would explain why is was especially weak.

In the AM broadcast band it is expected that the SNR (signal to noise ratio) is externally determined when using some sort of antenna, which includes what you described. In other words, you have not done anything wrong - the probability is that the signal is too weak. Of course, if you have the room for one or two km of beverage antenna pointing at Chicago, the results might change, but I doubt it.

Jeff,
How about finding a circuit for a pre amplifier for the MW band and building it, I am sure that will make a difference, but if there is a strong or a local station, it may swamp the receiver, but then you could construct a trap.

Over here one can receive AM stations at that distance during the day, but I guess it depends on how my RF crud there is in your area..

Two questions, what is the power of the station you are trying to receive? What type of a receiver are you using?

Another thought is to decrease your coax length and increase the amount of bare wire, more wire in the air the better.

You have two elements each located with x,y and z co ordinates at
each end, so you make your own file to suit the program you intend to
use or is available.
Surely you can model anything if you know the end locations of the
elements. If you are unable to do that then may be it is better that
you don't. There are to many programs around for me to make files for
every body and every program that is available so I supplied x,y,z co
ordinates which every body can translate.These are the points you
should look for to determine what the antenna looks like. Either way I
have supplied the results to save you the work.

I suspect you would be much better off using a small receiving loop.
But there are many variables such as time of day, etc.
For instance good reception of that station 100 miles away should be
a piece of cake in the daytime if you used a loop, and using ground
wave reception. A random wire is usually not the best antenna for
such a case. You have no way to null out unwanted stations.
At night, things change quite drastically, and you may or may not
have good reception due to additional interference from skywave
stations. But even at night, I think you would have the best results
using a loop vs a random wire. The ground wave never changes from
day to night. It's always the same. But the sky wave stations will
constantly be changing, and those are the ones that will ruin your
ground wave reception of the desired station.
The trick will be to reduce the reception of the offending stations
down to a point to where you can cull out the ground wave from
670. If you can do that, the reception of 670 should be fairly
reliable.
I know I generally have no problem doing this with stations 100-200
miles away, assuming they have the power and pattern to have
a decent ground wave signal at your location. And if 670 is a
50KW non directional as one claims, it should be fairly easy.

I remember doing a test comparing small loops to larger
verticals and horizontal wire antennas. You might find this
interesting. The audio files are still on my server, and you
can actually listen to the difference between the various
antennas as I switch between them.
Also the frequencies I'm using are also in the lower end of
the MW band.

Quote from old post..

> I have this feeling I don't know what I am supposed to experience from a
> working loop.

> Anyone have a mp3 file which can show what happens using a loop?

Here is one I did in 2002 comparing my 16 inch circle loop
vs my T vertical on the BC band.

I did a few quick comparisons between a 16 inch loop, and my "T"
vertical, which is about 42 ft tall, with a 120 ft long flat top wire.
It's pretty hot on MW. The radio was my ic-706mk2g. I'll let the
recordings speak for themselves.
You can click on the URL for the sound files, and your media player
"should" bring them right up and start playing. Hopefully anyway...

I did three tests, on three different frequencies, at different times
in the evening. I'm in Houston, and used mainly San Antonio as the
"target" city. "good 200 miles away" I recorded each test. I did
compress the audio greatly to save d/l time, but the audio is still
good enough to tell which is best. The files are pretty small and will
d/l quickly. They were huge files in the original sample rate and
format...I will "narrate" each test, so you will know which antenna
was used, and the exact times I switched. You can use the counter in
the media player to keep track of the time.

Test #1 was at about 7:30 PM on 550 kc.
http://home.comcast.net/~nm5k/mwtest1.mpeg
"Time in seconds"
0-13 -----loop
13-26 -----wire
26-38 -----loop
At 38 seconds I nulled the station, so you can hear the null.
46 -----loop, back pointed to the station
57-69 -----wire
69-end -----loop

Test #2 was at about 8:00 PM on 680 kc.
http://home.comcast.net/~nm5k/mwtest2.mpeg
"Time in seconds"
0-11 -----loop
11-23 -----wire
At 37 seconds I nulled the station
46 -----back pointed to the station
55-67 -----wire
67-end -----loop

Test #3 was at about 9:00 PM on 570 kc. Multiple stations on this
freq...
http://home.comcast.net/~nm5k/mwtest3.mpeg
"Time in seconds"

0-10 ----loop
10-23 ----wire
23-37 ----loop
37-48 ----wire
At 62 seconds, I turn the loop 90 degrees to get a totally different
station.
At 74, I turned back to the first station.
85 ----turned back to 2nd station again
91 ----back to the first

Here is another one on the BC where I turn the loop to null the
station.
http://home.comcast.net/~nm5k/mwtest4.mpeg
At first the station is nulled, and you can hear
a Mexican station in the background. At about 12 seconds,
I turn to the desired station. At 20 seconds I switch to
the T vertical. At 30 seconds I go back to the loop.
At 40 seconds, I null the station again.

End of old post..

Anyway, I'd try a MW loop.. It's going to be your
best bet.
One fairly simple design using PVC for the frame..
http://home.comcast.net/~nm5k/loop5.jpg

Hello, and a loop should be worthwhile. I've seen folks selling MW
receiving loops at Hamfests that consisted of a requisite number of
turns installed inside a plastic (mini hula-hoop) loop with a variable
capacitor for tuning. These loops were intended to work with a portable
radio (the radio is placed inside the loop). It is remarkable how the
sensitivity of a cheap portable radio is increased by the addition of a
simple tuned loop. This configuration should allow usable reception of
a 50kW AM station 100 mi. distant. BTW, the WSCR AM 670 website
indicates they also stream on the web. Sincerely, and 73s from N4GGO,

WSCR is a "Class A" 50 kW, omnidirectional station with no other stations close enough geographically to cause co-channel interference to their daytime groundwave signal even 150 miles from their transmit site (at 41 56 North, 88 04 West). They use a 182-degree vertical radiator.

The FCC's groundwave propagation curves for WSCR show that about a 2 millivolt/meter field intensity should exist at your location maybe 110 miles away, over the 8 mS/m ground conductivity for that path. Normally that field intensity should provide fairly noise-free reception even on an inexpensive, indoor clock radio. Other things equal, your daytime reception quality should be nearly identical for WSCR and WGN (720 kHz).

You might try using a vertically-polarized receive antenna, as that is the polarization being broadcast. It doesn't need to be high above the earth - in fact the lower end of it can be nearly touching the earth and connect to the center conductor of your coax, with the coax shield going to a good r-f ground. The required protection from nearby lightning strikes should be used with it if it installed outside.

The loop antennas suggested by others may work well, as they are vertically polarized for the E-field (as is the loopstick of a typical consumer-type AM broadcast receiver).

One other possibility is that a local noise source produces more interference for you on 670 kHz than on the other channels you're trying to receive. That will take some investigation.

Good luck,

RF

To correct myself, loopsticks respond to the magnetic field of an EM
wave -- which, for vertical polarization, lie in the horizontal plane.

Try disconnecting the ground rod at the tree and connect
the braid of the coax to the antenna input. Ground the
radio.

Thanks for all the replies and help. I did try grounding at the radio but I disconnected the shield at the radio not out at the outdoor connection. I'll try Jitt's suggestion. I've goggled around on constructing a loop antenna and it looks do-able for me so I may try that.
Most of the information I used to construct the long wire came from this link http://www.hard-core-dx.com/nordicdx/antenna/lab/coupler.html the author also describes a coupler which I may attempt if I can scrounge the parts unless anyone knows if something like that is available commercially.
Also could somebody recommend a lighting arrestor that would work with the RG-6 male and female connectors where the long wire connects to the coax.

Fiddling with the long wire, couplers, and tuners will change both the signal and noise by the same amount, which won't help you at all. You might as well turn your volume control up and down. A loop, however, gives you the ability to improve the signal to noise ratio by decreasing the noise from some directions, so you can hear the station better.

What make/model radio are you using?

If you have an option to tune in broadcast band AM stations using SSB
(sideband)
you may improve reception at the cost of limiting audio quality.

Steve

Got it on the loop antenna thanks Roy Lewallen, W7EL, sounds like that's what I need to start researching. My radio is just an older RCA 5.1 surround sound, I've got a ton of music vinyl and digital and use it mainly for that, but it's in my shop where I'm the boss and can smoke cigars if I want and where I listen to most of the baseball. I don't really care much for the RCA radio because I don't like the digital tuning, if I wanted to get a descent radio for am reception what's a good choice? I've got a couple older portables a GE Super Radio and a Midland 8-band, but I'd like a table model so I can take advantage of the surround sound and speakers I've got throughout my shop.

I wouldn't bother with the braid on the coax, use it as one long wire!
50feet is far too short, it's not resonant, you would need about 3 times
that.
You could also try loading the aerial with a large coil of wire or use an
ATU.
Be aware an ATU doesn't match the antenna as such, it doesn't make it
resonant, it only acts to make the reciever see 50 ohms. The aerial will
still remain unresonant!
Other than that, go to www.reciva.com and get the station via the Internet.

Hello, and this is a common misunderstanding, which may owe to the fact of the response of a receiving antenna in a near (induction) field of a transmitting antenna. In the far field (several wavelengths or greater) from the transmitting antenna the receiving antenna responds to the propagated electromagnetic field. Now, how a particular antenna is oriented wrt this EM field will determine its ability to extract a given amount of available power from the incident EM wave. One can of course think of the action of loops or dipoles in the far field as per Richard's statement but that sidesteps the underlying physics. Sincerely,

People get way too wrapped around the axle in in what they want
themselves called.

You see it all the time, as in say with developmentally challenged
people. For a while, we were supposed to call tehm "special" before that
it was "slow learner", at one point it was "retarded".

There is even a list of names that correlate to different IQ levels and
abilities, such as moron, imbecile, and other similar things.

But at the moment, it's developmentally challenged.

And those who would deride such folks will pick up the new term, and
eventually it will become bad to call people developmentally challenged.

Now as for the Amateur in Amateur radio, there is the idea of Amateur as
"devotee" or "admirer" and then there are others.

It's interesting that some folks would choose a descriptive term that
includes the synonyms:

Dilletante
Dabbler
Tyro

I especially like the Dabbler, that suggests desultory habits of work
and lack of persistence

or Tyro that implies inexperience often combined with audacity with
resulting crudeness or blundering.

All synonyms for Amateur. All right there in Merriam Webster's

But I don't give a good rat's patoot. Call me a Ham, call me an Amateur
radio operator. I'm comfortable with what I do, and don't need a name to
define it.

Others might be a tad more sensitive.

Fine. My interpretation of Amateur is a person who cannot do things in a professional manner, a person who is interested in something, but for lack of intelligence, skill, persistence, or talent, will never become proficient in what they are interested in.

Therefore, everyone has to accept my definition of Amateur radio operators as unskilled incompetents, eh? Especially since that very thing can be found in the dictionary, not an interpretation, but as synonymous with the word.

Now that would be sad, wouldn't it?

Names - Bah Humbug!

The GE Super Radio is what I normally use to catch baseball on am 670, especially at night, but after about 10pm local time I get a Mexican station overpowering 670. I'm aware of the internet option but MLB doesn't allow broadcasting, they want you to buy their MLB network subscription. But anyway the ideal setup for me would be a good am table radio and antenna setup that I can input to my stereo system and not fight with Mexico over the channel.

Dear Jeff D.: Now we have the needed information. You do not have a signal to noise issue but do have a signal to interference issue. Thus you need a means for reducing the strength of the XE station as compared to Chicago. .... and we are back to a loop antenna.

The angle between the XE station and Chicago is large enough probably to allow you to reduce the signal to interference ratio to an acceptable level with some rotating of the loop.

That's why I ask about the GE, if you can get it to work, you can
cobble audio into your stereo.
Regarding the interfering Mexican station, this a great application for a
loop, you can turn it to null out that offending station.
Even without a loop you should be able to turn the GE to null out the
Mexican Station.
Method;
Rotate the radio so the long dimension points at the Mexican station
(caution it might be in Cuba) :-) When you find the correct aim the audio
from the offender will attenuate. Also sometimes it helps to
tip the end that point towards the offender up a little.
Mike
PS. I hate it when baseball preempts talk radio programs:-)

This is especially apropos during the winter Olympics, where amateur athletes are competing. They look proficient to me. But then, I'm just an amateur myself. A ham, even.

> installation of beverage antennae?

May I point out that the beverage can be duplicated by winding in tight helix form such that it can be rotated on a tower.When made in garbage can shape the bottom acts as a reflector.
This provides multi polarity reception. Wire used can be zip cord or multi ribbon wire. The next step up from this design is if one adds electrically connected vertical wires so that it emulates inter woven wire (insect wire) which thus becomes a Faraday shield and is sensitive to all polarities. The helical wound beverage falls short by one polarity and short of a Faraday shield as the longitudinal spacing between the wound wires allows for wavelength penetration between them. Gains is in the same order as two FW radiators in equilibrium and both resonant as described yesterday on this newsgroup.Both of these designs may be placed close to the ground as with the beverage and may also be tilted in the vertical plane for maximum advantage.

Several years ago I was in a second floor apartment with a balcony.
Someone had previously bolted a 3/8-24 antenna mirror mount to the
balcony rail.

I used a 40 Meter Hamstick mobile whip with no additional ground plane
or radials. The Kenwood TS-690S had a built-in tuner that seemed to
work OK. It didn't get out very well, but I was on the air.

I expect it would have worked better on higher bands, probably great on
Ten or Six Meters with the appropriate whip.

As others mentioned, the origin is probably based on military standards.

It is my understanding that the lowest loss air dielectric Co-Ax would
have an impedance of around 75 Ohms. If you use the same mechanical
dimensions but with a polyethylene dielectric, the impedance becomes 52
Ohms.

Making the antenna resonant won't help your signal/noise ratio at all. And it makes no sense to make the antenna larger to increase the signal (and noise), then adding an attenuator to decrease it so it doesn't overload your receiver.

> OTOH, a loop might really help you sort out the competing signal.
> . . .

Yep.

A lot of amateurs get confused about the requirements for sending a strong signal and those for receiving signals clearly. At HF, they're quite different. And a lot of amateurs have the mistaken idea that there's something magic about an antenna being resonant. That confusion is why you keep getting advice to make your antenna longer, higher, and resonant, while those aren't the solution to your problem at all, and in fact are likely to create additional problems due to receiver overload.

Just let it drop!
I use Minninec not NEC programs
I really do not want to fight with you or anybody on this even tho
many want to.
I made the post as a point of interest and to share only. To show
what polarities it was sensitive to even tho many want to fight
regardless of what I post.
The majority on this newsgroup are not able or interested
in modeling which is why I posted the results, otherwise the intent
would be lost on them.
Ever since I declared that a static field in equilibrium, when made
dynamic, is applicable to Maxwells equation for radiation it seems
like everybody wants a piece of me even tho they are completely
ignorant of the physics involved. The model provided is complete
evidence of this fact which as yet nobody has been able to refute
prefering to personaly harm the messenger. Maxwell gained fame just by
adding /dt to an equation which made it dynamic,
and apparently many on this newsgroup want to deny him of his
achievement because the importance is not illustrated in any physic
books. Frankly, if you can't live with history you should be
challenging computer programing that utelise 1/2 wavelength radiators
where the energy lost by the components is ignored as is the EXACT
length of a 1/2 wavelength which varies with every cycle!
Use of Maxwells equations are for radiator designs that are sensitive
to ALL polarities directed at it for maximum efficiency, and not for
those designs that it ignores or cannot handle.

I have a (home built) 40 m ground plane with the base elevated about 8 feet and with 7 elevated sloping radials. The 50 Ohm feedline drops straight down the 8 feet and then runs on the surface of the ground.

Would a choke balun at the feed point be advisable?

Hmm, do you get a good null? Sometimes environmental materials can
mix the signals and you don't get a good null. See if you can take the
GE radio outside away from the building and get a null on the Mexican
and a better signal on your prefered station. If not I don't see where a
larger loop is going to help.
Just had a thought, If the Mexican station is actually a Cuban then trying
to null the Cuban would also null the Chicago station. They are about 180*
apart on either side of you. I'm in Fl. the Cuban stations are my
interference.

>
> It is my understanding that the lowest loss air dielectric Co-Ax would
> have an impedance of around 75 Ohms.

loss, at constant frequency, is proportional to
1/Z * (1/b + 1/a)
b= diameter of outer , a = diam of inner

This reflects the fact that at lowish frequencies (HF), the loss is
ohmic, so it's the series combination of the resistivity of the center
and outer conductors (the 1/b+1/a term), and the current flowing (the
1/Z term.. higher Z means lower current, so less IR loss)

Z is proportional to log(b/a)
so
loss = k/log(b/a)*(1/b+1/a)

Run the numbers and you see that a ratio of 1:3.6 gets you 50 ohms with
epsilon=2.3 and a ratio of 1:6.7 gets you about 75 ohms.

At 10 MHz loss is about 0.028 dB/meter for the 50 ohm, and 0.017
dB/meter for the 75 ohm.

but you can go higher in Z...and the loss keeps going down, but even at
1:20 diameter ratio, the impedance is 118 ohms, and the loss is 0.010
dB/meter. So 75 isn't a "lowest loss" frequency. More likely, 75 ohms
happens to be close to 72 ohms, which is the characteristic impedance of
a dipole in free space, or, more usefully, 1/4 of the 300 ohm impedance
of a folded dipole.

In air, the dimensions and loss are:
50 ohm 1:2.3 0.033 dB/meter
75 ohm 1:3.5 0.019 dB/meter

If you use the same mechanical
> dimensions but with a polyethylene dielectric, the impedance becomes 52
> Ohms.
>

I think that is just coincidence:

Z = 138/sqrt(epsilon)* log (b/a)

air has epsilon=1 (or very close)
polyethylene has 1/sqrt(epsilon) about 0.66, so, in fact, it happens to
work out (e.g. 50/75 = 0.66)

total bs. besides not knowing the difference between polarity and
polarization, the rest of the post is gibberish. one of the main
features of a Beverage is its polarization discrimination which helps
reduce noise and the linear shape provides directivity.

it wouldn't hurt, but unless you have problems with rf on the feedline
getting back into the shack i wouldn't bother.

p.s. it might also help if you are picking up local noise that is
being conducted on the shield.

The location is in the boonies of northern MN and is generally very
quiet. I am more concerned about disturbance to the radiation
pattern.

If rf is on the feedline, to a noticible degree, there is an easy indication I have found and think worthwhile to look at. That is, a field strength meter placed at a strategic point to make it more "susceptible" to the rf on the feedline. Now move the feedline. If the feedline is carrying enough rf to worry about, you will see it, at least, that has been my experience.

The only problem with the above are those "weird" antennas where the feedline actually plays a role in the antennas performance ... so, use with caution.

I don't believe rf on the feedline is what you want with your groundplane.

Regards,
JS

I hate to support Art, but he did give the endpoint data in picture6. I modeled it with eznec+ 5 and the pattern and gain are reasonably close to what he shows in the other "pictures". Close considering he appears to be using mininec and if he includes conductor loss and real ground it's off a fair amount (I show 9.36 dBi gain). I didn't run circular, and doubt that it has much in the way of circularity, which is kind of obvious from the elements. Even though they are skewed in a way which he probably patented.

I got the same gain as you using lower segments but it went up when I
doubled the segments so I held to that figure. I thought I provided
the cp and it was something like 3 dbi down which is much better than
20 dbi or more down if the array was not sensitive to cp. The same

segment problem occured again when modeling the
Beverage in circular form as it requires a tremendous amount of
segments to get total accuracy but the actual antenna in practice
showed conformality to make me comfortable. The same problem occurs
again using wire mesh and it would cost me near $1000 to acomplish
that but in practice it functioned very close to the circular wound
Beverage. The best antenna in the trials appeared to be long dual
wire mesh curtains which I checked out on top band tho conditions were
not consistent to hang my hat on. I intent to check out the "tilt"
action during the coming year using "garbage can" shaped mesh and at
ground level.
The whole point of the modeling was to show two FW elements that were
not planar or parallel provided an array that was sensitive to more
than a yagi built for horizontal gain alone. This to my mind makes it
a more efficient antenna for conversion of signals that hit it.
Another interesting point showed up with the circular beverage which
clearly merges the two vector radiations instead of the saucer shape
radiation from the earths rotation vector
and the gravity vertical column radiation that is added to the above
to form a planar yagi radiation form.

Picture6 data show equal horizontal and total gain, which means it's purely horizontally polarized in the direction of the analysis. That's also consistent with equal CW and CCW (or right and left hand) circular components, which mean polarization (again in the direction of the analysis) is purely linear.

if you wind a wire into a coil it is NOT a Beverage antenna. And note
it is properly Beverage with a capital B since it is named after it's
inventor. go invent something useful and make up your own name,
don't try to distort a perfectly good antenna that has well know
characteristics.

I don't even try indoors because it pointless, I go outside, but I've got some geographical problems being in a valley that's in a pretty dense woods. The Mexican or Cuban station has a period to it's interference, it's about a 60 second interval with a 20 second duration. I've been following the White Sox for 50 years and they've been on almost every Chicago am station, 720, 780, 890, 1000 but 670 is by far my biggest challenge to get good reception. I'll be happier when they move to another station.

Hello,

When that 7 radials don't touch ground and are about 1/4 lambda in
size, you have a very good floating ground. It will depend on the
length of the radiator whether you get significant voltage between
your floating ground and Earth.

When using a 1/4 lambda radiator (or longer with a series capacitor
and transformer) in my opinion you don't need it. During JOTA we use
a 0.4 lambda radiator over 6 elevated quarter wave radials (7..8 ft).
Last year we only used three of them. Moving high impedance cores
(for 7 MHz) along the coaxial feeder did not change VSWR. Also a good
diode probe with whip didn't show common mode issues with the coaxial
feeder.

Best regards,

Wim

Thanks Roy. I was rushed at the time and also didn't care too much,
since it was obvious that even though the elements weren't parallel or
on quite the same centerline, they were very close to it. He picks at
nits when he says his antennas are different. I could get similar
results from a good windstorm.

I don't know what your competing design would be but it avoids the
point that I am making.
By using the method where all elements are resonant and in equilibrium
proves the point of existing laws point to a dynamic field of
particles solvable by applying Maxwell.
One can thus see that accepted laws point to particles and not waves
in communication.
Extending these same points show that one can also manipulate both
elements in to smaller volumes while retaining equilibrium which

industry is now striving for. Probably, this can be done now by changing the radiaters into contra wound coils while retaining equilibrium.
Radcom of the UK showed an example of this some years ago when coils of wire were placed on a paper lunch plate which was exciting a neon tube placed above it. You would need a very large computer program to emulate this and that costs money. It also shows that the Standard Model consists of just two forces as the same two vectors follow the trail
of Newton's laws back to the "big bang" where the boundary fractures momentarily in trap door fashion to produce the same two vector forces of direct and occillatory helical rotations. The energy flow as envisaged by Einstein to prove this point is outlined on my page. One can also deduce from the above that the present speed of light cannot be exceeded unless a diamagnetic particle is found with less mass than that of a electron particle. None of the above is suggesting that the Yagi design should be abandoned by hams.

599. Two coax as substitute for open line

Newsgroup: rec.radio.amateur.antenna

Let's suppose that we use to identical length of coax, and on each
one, we connect the shield to the inner conductor at each of its ends.
If we use these two independant (?) sections as a substitute for an
open-wire line, could we use the usual formula Z=276*log(2S/D) to
compute the impedance of that line?

In that case, the characteristic impedance Zo of the coax could be
neglected. And what about the matched losses in dB/100' of the
resultant line? Twice the one of the coax?

Pierre,

The formula you give is an approximation which is not good for low Zo, and it ignores the effect of the dielectric (coax jacket).

I have seen discussion of this recently in another place.

Yes, you can fabricate a two wire open line like this. You need to find a way to bind the two cables for consistent physical spacing, if the jacket is PVC you are using a lossy dielectric, the braided conductor is lossier at RF than an equivalent solid copper tube. So an expensive low Zo line, not a low as you might think, with poor performance.

Why would you do this?

Owen

Pierre,

The matched loss of the resulting open-wire line is not related to the matched loss of the coax cablebecause those cables are not individually operating in "Transmission Line" mode. For the same reason, the velocity factor of the open-wire line will not be the same as the coax.

Here's a write-up of an experiment I did to produce low Zo balanced line. I didn't measure the loss because my application was for a very short run:

Steve, you haven't let on much detail about the application of your low Zo line.

I think I suggested elsewhere that you could fabricate such a thing with parallel coaxes with all of their shields at each end bonded.

I explored using square tubes as a rigid transmission line. This finds application in a range of areas, eg the boom of a LP. See http://www.vk1od.net/calc/tstl.htm . A 50 ohm line (if that was your objective) requires an air spaced line of 1.19 D/d. The article contains a calculator to solve the curve fit.

> air has epsilon=1 (or very close)
> polyethylene has 1/sqrt(epsilon) about 0.66, so, in fact, it happens to
> work out (e.g. 50/75 = 0.66)

Agreed that (ignoring loss in the dielectric)

loss(dB) = k * (1/a + 1/b) / log(b/a)

k includes a factor for the permittivity of the dielectric, a factor
for unit length of line, and a factor for the units of a and b.

Now assume a fixed outer diameter b; does this function have a minimum
versus a? Let k=1 and b=1 for convenience (won't affect the ratio b/a
at minimum). So, find "a" to minimize

y = (1/a + 1)/ log(1/a)

I get that to be b/a = 3.5911 or so. It doesn't even matter if you
use log10 or natural log; same result. This says that loss for a line
constructed the same but with a larger b/a and same b will have higher
loss.

With vacuum dielectric, the impedance of coax with that 3.59:1 ratio
is about 76.7 ohms. With solid polyethylene dielectric, it's about
50.6 ohms.

I didn't see anything in your dB/meter numbers about line diameter,
and that's clearly important. You can make the line bigger to get
lower loss, or smaller and get more loss. Clearly if I keep "a"
constant and let "b" grow to get higher impedance, the predicted line
loss will go down monotonically with increasing b/a; things fall apart
when b becomes a significant fraction of a wavelength, of course.

If I calculate the dB loss for air-dielectric lines of several
impedances, all with the same outer conductor inside diameter, and
ratio the results, here's what I get. Note that the attenuation

doesn't really change much with impedance until you get to fairly high or fairly low impedances. Also...simply multiply the Zo numbers by 0.66 to get the ratios for lines filled with solid polyethylene dielectric (again assuming no loss in the dielectric itself; generally accurate up to at least several hundred MHz).

Zo (dB/unit length @ Zo)/(dB/unit length of 76.7ohm line)
25 1.682
30 1.475
35 1.333
40 1.231
45 1.157
50 1.103
60 1.035
70 1.005
75 1.000
80 1.001
90 1.018
100 1.052
120 1.168
140 1.350
160 1.607

One shouldn't read too much into these numbers with several significant figures; line attenuation also depends on things like whether the conductors are solid or stranded or braided. Stranding and braiding adds to the loss.

'Nuff for now...

Cheers,
Tom

I certainly agree with Owen that it's not a particularly good way to get a low-loss two-wire balanced line. To me, the attraction of a two-wire balanced line is the low loss when it's properly implemented at relatively higher impedance. That said, however, one can buy "Siamese twin" cables with two pieces of coax in the same jacket, arranged to make it easy to separate them. The web of jacket between the two lines is relatively thin. Such line is common in CATV installations in homes.

At low frequencies (HF, especially lower HF frequencies), the dielectric loss may not be too bad, especially for the low impedance involved. It may be a cheap way to get an approximately 100 ohm balanced line. Even though the braided conductors will have higher loss than equivalent diameter smooth conductors, the copper loss for

typical RG-6-type line used that way (about 5mm OD outer conductor) will almost certainly be less than that using, say, 2mm diameter solid conductors. You may be able to find surplus (e.g. reel-ends) of this sort of line at very attractive prices. Even new, it's not too bad--a lot cheaper than equivalent diameter solid copper!

Cheers,
Tom

I understand the Navy used to have some coaxial line you could drive
through. The center conducter was hung from huge ceramic insulators
similar to those used by the power company.

Owen.

The application is no secret - the first paragraph in my linked page
explains it.

I was looking for line with a Zo in the range 50ohms-70ohms that could
be used for the band interconnects on the hexbeam. Arguably, balanced
line would be easier to handle, and might have some common-mode
advantages. Total length is about 4ft so loss is not an issue. It
would need to be very easily replicated, using materials readily
available to constructors world-wide.

At the end of the day it became more of a "self learning" exercise
than a serious quest !

In the ARRL's Antenna Book 21st ed page 24-21, we see that if we connect the two shields of the coax cables together, we obtain 'Shielded parallel Lines' . In that case, the resultant impedance is simply the sum of the characteristic impedances of each coax.

So, there is quite a difference between the two independent coax I mentioned in my first message (we connect the shield to the inner conductor at each of its ends) (A) and the 'Shielded Parallel Lines' case (B).

I am trying to understand why and it is the reason I posted my first message...

In (A), the Z=276*log(2S/D) applies, so the Zo of each coax does not matter.. but in (B), Z=Zo1+Zo2, so the value of each Zo matters.

Am I right? And how to compute matched line loss in case (A) and in case (B) ?

If you tried my calculator for the square tubes, you would have found
that you get lower Zo for the same D/d ration as for round tubes. For
example, a pair of 12mm tubes clamped together with 2mm spacing gives Zo
of around 50 ohms. If such an element could be used to replace one of the
spreaders, then you have neat solution... but it would take some custom
moulding to support such a spreader on the hub.

That is not quite what you asked.

However, in the case you described in your first post, the shield of each cable carries the differential current on the outside of the shield.

In the case of B above, the differential current is carried entirely inside the shield, no differential current flows on the outside of the shield.

So, the field structures, and therefore Zo are different in the two cases.

I opine that you will have to measure MLL for case A, mainly because the effective RF resistance of the braid is not easy to estimate.

(B) can be found from tables, or better still, http://www.vk1od.net/calc/tl/tllc.php , it is the same as the single cable used to fabricate the pair... think about it.

Is there no data for the RF resistance of the center conductor vs the
RF resistance for the braid? One would think it could be ascertained
by comparing known coax losses to known parallel line losses when the
wires are the same size.

Sounds kinda messy and unstable, to me.... but do-able I suppoes. I'd rather search for a few short pieces of 25 ohm coax and do the coaxial balanced line thing as normally done.

Ok, revisiting things now that I have time, I discovered something,
which The Art may (ok, will) get off into an incomprehensible rant about.

I did a simple normalization. I calculated the lengths of the elements
and the location of their centerpoints. I then calculated the distance
between the centerpoints. I then put it all in a nice level and square
2 element array. I left the diameters alone.

New endpoints -

-37.455 -219.135 707 -37.455 219.135 707 1
37.455 -195.45 707 37.455 195.45 707 1.25

Results at 14.175 using EZNEC+ 5

Gain F/B
Original 9.87 dBi 7.84
Normalized 10.29 dBi 8.58

The impedance curves were not different enough to be of note and were
matchable to 50 ohms with good efficiency.

I'll take the one with better gain and F/B that's also nice looking with
elements that are easier to mount because they're at 90 degree angles,
thank you. Yes, run-on sentence.

>Original 9.87 dBi 7.84
>Normalized 10.29 dBi 8.58

I wonder whatever happened to the golden city shining on the top of
the hill that Art called "length efficiency?" A back of the envelope
calculation of Art's 20M antenna reveals elements that are
conventional half wave. This raises the more immediate
head-scratcher: whatever happened to the golden calf of his designs
being in equalithium?

Tom I have no problem with your choice of going with the one with the
best front to back, what ever one that is. The crux of the matter is
under the equations of Maxwell optimiser programs do not provide the
```

planar form as the best radiator. I understand that Roy now has an optimiser program for sale and I fully expect for it to follow the same pattern as well as prove my point on the circular wound antenna as apparently he supplies more than enough segments assuming the computer has the power to use them.
However a look at the larger picture the same particulars provided state that one can manipulate the elements to occupy a small volume as long as the resonance and equilibrium restrictions are held to. I see that as the real prize that will come from my workif one had the equipment to do the optimization. Ofcourse if Roy's program still provide the yagi as the optimizer result then there is a definate conflict with other computer programs that use Maxwells equations.
Looking back at the idea that waves are the carrier of communication it leaves us with the silly propersition that a Faraday cage perforations must be less in size to that of the incoming wave! Thus for a cage for use on the top band
can live with openings that are a bit smaller than 180 metres! Now some text books have dropped the size opening to approx 1/10 of a WL which is still way to large to enclose the eddy current rotation.Einstein failed to prove his theorem and was forced to invent quantum mechanics which provided the answer of particles that he anticipated and now with the above standard physics figures supplies the same result. So it is up to the ham himself to decide whether it is worthwhile to have an antenna sensitive to all signals that are thrown at it, where it operates in a smaller volume than the yagi or stay with one more pleasing on the eye. I personally do not have the equipment to pursue what appears to be smaller antennas than presently used all the way down to point radiation.
What hams have to recognise now is that the much vaunted antenna programs do not consider the yagi as an optimized array and to decide whether to ditch the programs or pursue what the programs based on Maxwell provide to its limits.

Richard,
I am sharing results provided by computer optimizers where an array
must be in equilibrium. I am not party to how these programs were
generated or how closely they adhere to maxwells equations.If they
provide results that are different then that seller has to answer for
it.
Obviously clever people such as yourself will guide hams on the
correct path to follow
as well as to explain why Maxwells equations do not favor the yagi.
Hopefully you will supply technical details and not just wordy fluff.
I would point out that Tom provided a planar form, which you copied,
for a different frequency to the one that I supplied which provided f/
b/r that greatly exceeded his design. If your idea is to be a pied
piper to lead ham radio away from
examining change then such tactics will certainly do the job. But
first to justify your dreams as a leader you have to provide reasons
that make optimizer programs suspect.
A point in your favor would be that Roy declares that his optimizer do
NOT supply the results that others do so that experts such as you can
direct your talents where they would be more profitable. Since you are
not wired the same as I am I will not respond to you any more so that
guilt by association may not be applied. But I will mention to all
that you are in total disagreement with the association of a static

field being made dynamic which is a staple in physics around which this discussion rests upon. Nobody, nobody, has come forward to provide academic reasons why this staple should not be held to or why people such as you should trash pursuit of that what I disclose. What I have provided is that computer programs side lines yagis in favor of arrays where elements are not parallel but all are resonant and where the array as a whole is in equilibrium. They do this because Maxwell supports the physics staple I proffer which you declare as NOT being correct but without supporting data other than you said so.

Steve,

Another thought comes to mind, and that is a pair of rectangular
conductors, preformed to the parabolic like shape and screwed togeter with
insulated fixings.

You could achieve the Zo you seek with say 20mm wide flat with manageable
spacing... however it would be a water trap to some extent (just like LP
feeds using twin booms).

Well having just tried it for real on a network analyser, and simulated
it on Ansoft designer I am now convinced rather than being sure!!

Owen,

Thanks for the suggestion - water shouldn't be a problem because this
"band interconnect" TL can be installed within the hexbeam centre post
where it would be protected. One chap has already fabricated a "square
coaxial" version - second photo, here:

http://lema.epfl.ch/images/stories/LEMA/Members/zurcher/hexbeam/hexbeam_HB9MCZ_wb.html

but that will be beyond the capability of many constructors!

It's not a major issue - most constructors simply use RG213; but some
find the physical terminations "fiddly", especially if you try to
assemble it inside the centre-post for neatness and weather
protection. I'm pretty sure that twin line using the right gauge ecw
with teflon tubing on one of the wires would be about the correct Zo
and easy to fabricate. It's just another thing on my "to do" list - a
list which seems to get longer rather than shorter :)

73,
Steve G3TXQ

Seeing the construction, I think a pair of rectangular tubes would be
easier to construct, and raise less water retention issues.

I didn't realise that the line section is straight, I had visualised it
taking the shape of one of the spreaders if you understand what I mean.

Anyway, my recommendation would be like in the pic, but using two side by
side rectangular tubes, say 20mm with 4mm spacing.

That is not an explanation at all.

Your confirmation might just be confirmation of a wrong interpretation of
the B configuration.

I should have added that I would attach the coax at the bottom, and use a
ferrite cored broadband balun.

And you just might be wrong on both counts.

I will offer you an explanation of why the ARRL position is IMHO correct.

The configuration is a pair of identical coaxial cables, shields tied
together at each end, and the inner conductors used as a two wire
transmission line (http://www.vk1od.net/transmissionline/stcm/Fig02.png).

Question is what is Zo of the combination?

for each of the coaxial lines, its intinsic Zo defines the ratio of V/I
for a travelling wave at any point. If the two inner conductors are
driven by a differential signal, then I in one conductor equals -I in the
other (defined by differential mode), and V conductor to conductor is

twice V conductor to shield, so V'=2*(I*Zo), and
Zo'=V'/I=2*(I*Zo)/I=2*Zo.

I should have expected that this is not obvious to you Jeff, and expand that
to:

...
in the other (defined by differential mode), and V conductor to
conductor is (by definition of differential mode) V'=(I*Zo-(-I*Zo))=2*I*Zo,
and Zo'=V'/I=2*(I*Zo)/I=2*Zo.

There was an article published maybe 15 years ago (RF Design magazine?? Electronics Design?? EDN??), authored by a fellow from Andrew as I recall, about some of the finer points of coaxial cable. I thought it was quite a good article. He had "rules of thumb" for loss in stranded center conductors versus solid that I remember for sure, and perhaps for braid as well--I don't recall that for certain. It wasn't huge, just a few percent, for the stranded center. Of course in coax, since there's a lot more surface area to the outer conductor than the inner, the braid would have to be considerably worse than a solid conductor to significantly add to the total series RF resistance, so it wouldn't be trivial to resolve by measuring coax with a solid outer versus a braided outer. You'd have to go to considerable effort to keep the rest of the construction identical to nail down the contribution of the braid versus solid outer.

In any event, it seems a reasonable way to get a large diameter RF conductor that remains flexible...I'd be very surprised if a 5mm diameter coax braid was a worse two-wire line conductor than 2.5mm solid, smooth copper. I would want to keep the jacket on it, sealed against weather at the ends, to keep the copper clean.

Cheers,
Tom

I suppose what follows has already been covered, but perhaps different words to say it will help...

In the case of the two pieces of coax, used as coax, the fields are entirely inside the coaxial lines. The center conductors carry current, and as they have relatively little surface area compared with the outer conductors, they contribute most of the loss (assuming good dielectric with negligible loss). Balance depends on the load and how the lines are fed; there is nothing inherently balanced about the line itself. In fact, you could make such a line out of two pieces of coax with different constructions: same outer conductor diameter, but solid polyethylene dielectric for one and foamed polyethylene for the other. The result would be different attenuations in the two, and different propagation velocities, so that for the same physical length for each, fed 180 degrees out of phase, the signals at the other end would not be "balanced." Fed as a two-wire line, it would be balanced (assuming it's kept away from un-balancing structures). The effective impedance for two identical lines (back to the same dielectric, etc.) fed that way is just the twice the impedance of a single line.

In the case of the two pieces arranged with constant spacing, fed as a balanced line, all the fields are external to the lines. There is essentially no field inside the outer conductor of each line. The center conductors carry no current, so there is no particular need to connect them electrically to the outer conductors. The loss is

determined by the RF resistance to the current carried on the outside of the outer conductor, and by loss in the dielectric between the wires (or more properly, dielectric in the area around the wires where the electric field is significant). Since the fields are external to the coax (not used as coax), the impedance depends only on the physical configuration outside the coax -- not on the coax inner conductor diameter, and not on the dielectric inside the coax. Those are invisible to the fields carrying energy on the two-wire balanced line.

Note that it's possible to transmit three independent TEM signals on a couple pieces of coax configured as a two-wire line: one on each coax and one on the balanced line.

There's a useful formula for estimating the loss of coax or balanced lines. It includes a term for loss in the resistance of the conductors, and another term for loss in the dielectric. For coax using good dielectric, up to a few hundred MHz at least, the second term can almost always be ignored. In English units (conversion to metric left as an exercise...), it's:

A100 = 4.34*Rt/Zo + 2.78*f*Fp*sqrt(epsilon)

where
A100 = matched line loss in dB/100 feet
Rt = total conductor RF resistance (see below), ohms
Zo = characteristic impedance of the line
f = operating frequency in MHz
Fp = power factor of dielectric at frequency f
epsilon = permittivity of the dielectric, relative to air
(Note: Fp is essentially the same as the dielectric power factor for any dielectric you'd care to use in an RF transmission line.)

A good estimate of Rt for copper conductors thicker than a couple of skin-depths is:

Rt = 0.1*(1/d + 1/D)*sqrt(f)

where
d = diameter of inner coax conductor, or the wire diameter for two-wire balanced line
D = diameter of the outer coax conductor, or = d for two-wire balanced line

This formula is from the "Transmission Lines" chapter of Sams' "Reference Data for Engineers." You can replace 1/d and 1/D in the Rt formula with Rrf/d and Rrf/D for non-copper conductors, where Rrf is the RF resistance of the conductor relative to copper. Normally, that would be sqrt(Rdc(material)/Rdc(copper)), for non-magnetic conductors. So for aluminum, use 1.23 in the numerator for that conductor instead of 1.00. It is _probably_ reasonable to use 1.07 instead of 1.00 for stranded copper, and maybe 1.10 for braid, but "your mileage may vary."

Cheers,
Tom

Maybe a simplified approach to the problem would work. Visualize two
separate flat 50-ohm systems where Source2 is 180 degrees out of phase
with Source1, equal in amplitude, and phase locked.

```
GND=================braid====================
Source1----------------------50 ohm
coax---------------------------------50 ohm load1
GND=================braids==================Center Tap
Source2----------------------50 ohm
coax---------------------------------50 ohm load2
GND=================braid====================
```

Can the center tap at the load be disconnected without changing
anything?

Tom,

I have attempted to predict the behaviour of bootstrap coax traps, and an important factor is the effective RF resistance of the outside of the coax which forms an inductor.

My measurement capacity is quite limited.

Trying to reconcile my prediction with W8JI's measurements of such traps makes me think that the effective RF resistance is much poorer than a tube of the same size. Factors causing this would be braiding, proximity effect and dielectric losses in PVC jacket.

Owen

I think I'll be in good agreement with you, here, Owen, by saying that
the right way to find out about something like this is to actually
make some measurements on the configuration in question. Maybe I can
come up with something... I do have reasonable measurement technology
available, though getting it "right" isn't trivial, especially with
balanced open-wire line. I do have some ideas and if I can find time
will try a couple different ways to see if they agree. Time, right
now, will be the problem.

Cheers,
Tom

640. Re: Two coax as substitute for open line

Newsgroup: rec.radio.amateur.antenna

Source record: 10890

In a line made up of two parallel coax cables with connected shields and with the shields floating at both ends, let's suppose that one center conductor (cable A) is carrying 1A and the other (cable B) 3A, exactly out of phase with each other -- that is, the line is not balanced. The inside of the cable A shield will have 1A and the inside of the cable shield B will have 3A, again exactly out of phase, and each one out of phase with its corresponding center conductor current.

Let's consider electrically short cables for simplicity -- short enough that the currents don't change much along the length.

As Tom said, the fields are contained within the coax cables -- on the inside of each one is a canceling pair of currents. But at the ends of the cables, the shield currents can escape to the outside, 1A from cable A, and an out of phase 3A from cable B. The result is a net 2A flowing on the outside of the shield. This current will cause the combined cable to radiate exactly the same amount as if the shield wasn't there at all! All we've done is to physically separate the differential and common mode currents, but we haven't changed their values.

So what happens when the conductor currents are balanced, i.e., equal and opposite? Well, then there's no net current on the outside of the shield. Now there's no line radiation, again exactly the same as if the shield wasn't there. The shield likewise has no effect on reception of unwanted signals -- it provides no shielding at all. The only way to make it provide shielding is to block the current path from the inside to the outside of the cables at both ends. In the case of an antenna feedline, however, this would require putting the antenna into a shielded box.

The shield has an impact on the differential mode impedance, but it doesn't help line balance or provide shielding at all.

Has anyone tried one of these power supplies a Watson Power-Max-45-NF and are they any good?

How loud is the fan and is it a thermally controlled fan?

I have been looking for some reviews but I haven't found any.

Thanks

Patent number 1 on my page has now been approved . If there
is anything there then my grandchildren will benefit.
If there isn't you can visit my grave and say "I told you so."
Now I await the 2nd request to go thru.
Yes anybody can get a patent and yes you knew all about
that years ago and couldn't be bothered. And yes it doesn't prove
anything
at least at this point. So I have saved you from having to post. The
other spammers can now go right aheadand show who and what they really
are and add to their profiles.
Look up patent number 2 on my page and start storing ammunition ready
to throw my way.
With respect to gain comparison, what I am providing is sensitivity to
all polarizations thrown at the antenna instead of concentrating on
horizontal alone and neglecting receipt of all others. Gain is just
one measurement but it is nice if you can hear what others neglect
or not sensitive to or cannot hear. If you want to see a model of the
arrays in number 2 I can supply.

650. A static field made dynamic to make Maxwell applicable

Newsgroup: rec.radio.amateur.antenna
Date: 2010-02-27 04:08:59 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <50b13015-e445-47d6-b8b6-e1e8372813c5@g28g2000yqh.googlegroups.com>
Source record: 10900

I made a time varying field addition to a static field in equilibrium
some time back. All on this group said it was and still is B.S.!
It was this finding that created the basis of a new antenna science
that I have shared with this group and with page Unwin antennas.
If one goes to
http://www.james-clerk-maxwell.com/

one can read in better in detail a description of my findings in a
much better way than I can fully explain where a mathematical error
existed when changing from MKS units 150 years ago when utelizing the
laws of statics in antenna design.
My findings are in the patents loosely described on my page
Unwin antennas!
The author of the paper goes on to say how this error has placed
physics back to the middle ages or something like that and for my self
I have the feeling that this error was the sole reason for Einstein
not solving the Standard model before he gave up and moved on to start
the idea of Quantum physics. For myself I am very comfortable with the
idea that communication is by the "particle" as a carrier of the
charge and not the often much quoted "wave." In addition I would point
out that the array I gave in another thread is further proof of the
correctness of what I have stated which is according to Maxwells
equations where accountability
is made of all forces. All antenna text books as well as those in
physics will now have to be updated to reflect the above findings
I am so pleased that I have been found not guilty of spreading B.S. in
the amateur radio community and thus exposing spammers for what they
really are. In summation it is now possible to make antennas in a
smaller volume such that a radiator for top band can now be placed
upon a tower or in a small garden as envisaged by Mr Moxon who has
since become a SK.

Yep the mesh antenna is pure BS. In efficient antennas the DC
resistance of the antenna is usually quite small, values in the
1/100ths or 1/1000th of ohms would be expected. Normally the RF
impedance of the antenna is hundreds or thousands of times greater
than this. Under these conditions most of the power is going to be
radiated and only a small part radiated as heat. In the case of the
mess antenna the feed point impedance of the antenna is what you would
expect the DC resistance to be(around 1/100th of an ohm) . This means
most of your power is going to be used to heat wire. Congratulation

Art, you have made another Dummy Load.

Jimmie

No Jimmie, the function of a Faraday shield is not the same as a wire antenna. It's function is to cancel the arriving fields to obtain the time varing current which is the product of same
so it can be used by a radio. There are plenty of descriptions on the web showing how the fields are separated and then cancelled by the movement of charge which in turn generates the current that the radio can use. The movement to cancel each other is an accelleration of charge which is the prime mover of communication.

From Art's web page http://unwinantennas.com/

"THE NATURE OF LIGHT AND RADIATION WITH RESPECT TO PARTICLES OF THE
UNIVERSE

"The Sun is very hot because it is burning. Burning as we know it
produces soot and other by products in abundance that when these
particles collect in the air they become visual to the eye as smoke
even tho the particles themselves are invisible to the eye unless
there is a contrast in light as with particles passing thru a shaft of
light thru a window.

"The particles produced by the Sun are called Leptons where the
difference between them is the colour of light that they can emit.
Thus we have three types of Leptons each able to produce one of the
primary colours, red, green or yellow. Thus we have three types of
Leptons each able to produce one of the primary colours, red, green or
yellow. When the pressure increases beyond a certain point the Sun's
boundary is unable to contain them so they escape to the tune of
millions per unit of time and float to all different directions."

And so on...

yeah, i'm sure everyone would want to read it again just to get a good
laugh. almost as good as the aetherist's non-profit organization's
site. i wonder how many donations they get? maybe you should join up
with them art, you would probably fit right in with your 3 color
leptons that can't recreate the whole electromagnetic spectrum.... you
do realize that everything from dc to gamma rays are all the same
phenomena, electromagnetic waves, right? or are they just

manifestations of your magical levitating diamagnetic neutrinos?

Just the name of this thread is a good laugh..
IE: bend the rules so the error in thinking becomes truth. :(
Make Maxwell applicable for what? Contra wound dummy loads?
BTW, my cat has new zircon encrusted mittens.. :)

Yes, you are correct and I misspoke!
The point I was trying to make that space as we know it, yes free space, has a resistance value tha same as the carpet and balloons that I described earlier. This resistance gives substance that the atmosphere is a true substance or a dielectric and not just nothing or an empty space. After all, if it was a true nothing or vacuum then outside forces upon the boundary with in which it exists would compress that boundary until it really did not exist.
This same explanation explains why a plane or a satellite can transmit and receive a radio signal because in each case it qualifies as a Farady cage. As to whether we care or not is dependent on whether we need the outer layers around earth that sectionalize the boundary around earth because it is our boundary that hold the layers in position to provide frictional qualities against the communication particles. The bottom line is that the eather is not just nothing but a sea of particles separated by charge and can just as easily land on a sattellite or impinge on the high density magnetic field at our magnetic poles where light is created. I would also point out that the speed of light is determined by "white light" which thus limits the visible spectrum of light seen at the poles.
Bottom line is that our outer space is not just nothing but is a dielectric substance that has
a measurable resistance which puts us back fully into the camp of Newton from which we strayed 100 years ago. The mathematical error is real and just like a check book that doesn't balance time competes against its correction.Remember that all this is a result of illness which forced me back in years where my vocablery was that of a child and consisted of what, why, when, e.tc that reflects human curiousity and where one is forced to start from the same datum line which is one of first principles and not blind acceptance as our experiences and education system rewards.

I totally agree with using a loop antenna, though you may need to experiment with 'back shielding' [since you want to 'knock down' signals, coming from the undesired direction]. Too bad you couldn't latch on to some of the radio compass units, I maintained while in the USAF.

But, BEFORE screwing around with antenna connections [etc] get out your trusty AC voltmeter, and with the radio connected to power, VERIFY that none of the antenna connections/other exposed metal parts are 'live'. Older radios, particularly Shortwave units, had what is known in the repair trade, as a 'HOT CHASSIS'; where-in they lacked a power isolation transformer, & usually had non-polarized power cord plugs [both blades the same dimensions. Depending upon plug insertion, into the receptacle, it can put the full voltage of the power source, onto any metal, attached to chassis. Flip the plug over, and the chassis is no longer 'HOT].

Best to replace the plug with at least a newer version, with one wider blade. Or the latest '2 wire w/GND' style. Look at your receptacles, and note there is a longer slot (this is the a/c 'neutral' line {WHITE wire connection}, the short slot is the 'HOT' line {BLACK wire connection}, and if the receptacle is newer, it has the '3rd' wire round GROUND {GREEN wire connection}. If you don't know how to verify, find someone who does, like a member of your local Amateur Radio Club, Electrician, etc.

There is an inexpensive device to plug into the latest receptacles, and verify some connections; but may not always confirm that the GROUND/ Neutral are, in fact, seperated clear to the Utility Panel. Not vrifying, can result in DEATH.

A neumonic, to help remember proper connections 'BLACK on brass to save your ass', referring to the brass colored terminal. The WHITE goes to the silver screw terminal, and Green goes to {duh} the Green terminal.

NOTE: if your mounted receptacles are orientated with the Ground terminal UPWARDS, then 'WHITE on the RIGHT' applies.

As I'm both a 'diehard scanner enthusiast' & an Amateur Radio Op, I've found that you can use two cheap antenna rotators, with either an ordinary TV antenna [for scanner hobby] or a 2/70cm antenna [normal versus SSB]. The idea, being to use one rotator to 'bore sight', in azimuth, on the desired signal. With a suitably designed bracket, the other rotator controls the vertical/horizontal antenna orientation. Naturally, you only need 90 degrees for polarity change; and it goes without saying, be sure your elements clear all parts of your antenna and guywire supports. !!! 'Crunchy' sounds eminating for your antenna location, usually means $$$.

is that why its dark at the poles in winter? they run out of magical
levitating diamagnetic neutrinos? I thought the speed of all
electromagnetic waves was equal in free space.... but thats just a
pesky fact that you are free to ignore in your own little world i
guess.

Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

It is not unusual for those involved in physics to see engineers as
trash.
But physicist have relied so much on mathematics to the point of
covering up errors
that it is now really the science of plagarism.I don't know what your
achievement in life are
but it would appear you are talking as a physicist possibly with a
phd. Earlier we had a phd from MIT post that the error I allude to
is indeed an error which occured when the cgs system was replaced I
therefore suggest that you and others should scan the web with respect
to errors made in physics and how they have been covered up. I suggest
you start with the errors of Maxwell and follow thru to see how these
errors have been magnified via plagarism. I am an engineer and not a
physicist such as you which puts me in the position of being able to
check mathematics and discern mathematical errors. I gave you a paper
that echoes the mathematical errors that I pointed out in a much more
readable and scientific fashion. So with the extensive knoweledge you
seem to suggest you have why not critique the math presented in the
article and show to others from a physics standpoint the paper is in
error? This would be so much informative in sending a string of posts
to defame me which is an example of free speech since it has no
scientific analysis to prove your point. This is why I do not respond
to you since you provide no facts of interest only spam as with a few
others on this newsgroup. If indeed you do have a doctorate in the
subject or some notable achievement in this area you will have my
attention but at the moment the only evidence i see is one of spam.

Green is a primary color - RGB

However, what is primary for one discipline is not primary for another
discipline. For instance, in color photography and in its negatives,
the colors are Cyan, Magenta, and -ahem- Yellow. This is the
difference between additive primaries and subtractive primaries.

These colors are actually dual band modes
Cyan is Blue + Green
Magenta is Blue + Red
Yellow is Green + Red

There is also the opponency color system that contains, as colors,
Red, Blue, Green, and Yellow.

However, color is a perception and has absolutely no connection to
sub-atomic leprechauns. All light emanates from electron orbital
displacements (aka charge acceleration).

That he may be, but Green is one of the three primary colors. At least
in additive color mode Red Blue Green. If you are talking about
subtractive color, it is Cyan Magenta Yellow. Add black and it becomes
the standard printing system.

True, but the "primariness" of the colors in these various color systems are far from universal. These colors are "primary" only with regard to the visual systems of human beings (and some other primates) which have a particular type of three-pigment visual receptor system.

Animals which have significantly different visual pigments in their optic receptors (and there are many!) would tend to have a different response than humans to various mixtures of red, green, and blue light... e.g. the "red light plus green light equals a yellow color" mixing trick would not necessarily work for them, as this is a perceptual "trick" of the human visual system. Although human eyes may not be able to distinguish between a red/green mix, and a true narrow-band yellow, a spectrograph (or a simple prism!) will demonstrate that they're very different!

If Art is actually claiming that there's some sort of binding or correspondence between the three families of leptons, and the "three primary colors" as seen by humans, then the only such correspondence I'm aware of is that both have the number "three" associated with them. There's no physical correspondence deeper than that, to the best of my knowledge.

Thank you Richard for an explanation that I did not supply.
It also has not been ruled out that a lepton cannot change its
frequency
when it emerges from the boundary of the Sun until it arrives on
earth.

Either way it is a minor point in the discussion of communication.
It would be better if a separate discussion was posted for the
spammers as to how many colours are visible in the aurora beaurilas to
where the other colours come from and let them fight from there.

David I am not ruling it out since I cannot personally state there is
a lepton for every color or hue. What I am deducing that particles
arrive on earth in the millions per cubic metre serching for a place
to rest on earth recognising at the same time the connection between

light(colour and particles) W#e see evidence of this every day where they seek a diamagnetic surface one of which is water where they form a skin on the surface and where this surface can be transformed by the addition of soap. The whole discussion is really about the standard model which became visual to me when I added a time vary field to a boundary containing static particles. I was unaware at that point of the huge disagreements in physics about the errors of maxwell. Either way the only avenue I had to pursue my thinking was to assume that programmers had kept faithfully to Maxwells equations alone. When I got hold of an optimizer I operated it with toally disconnected figures so that I could not be accused of propelling an answer that I would like., The results are on my page showing clearly the requirement of equilibrium. I am not considered a skilled programmer and I am unable to fathom the truth of my program. As always I went to an academic out of state who was familiar with antennas and physics for verification by using other alternative programs where he confirmed my findings. Whether my attempt at the standard model may be worthless the arrays that I was lead to were new ,correct and probably of some use. They in no way represent an effort to disprove the duallity theorem
because that doesn"t state that the particle in question doesn't change form ,only that they have similar properties. Yes there are spammers attacking me but as yet nobody has proved that my deductions are not correct. I don't listen to spammers but I do listen to those who have a modicom of interest into how radiation works since the true answers are not in any of the books.On the subject of the word "soot" being rediculled it becomes obvious that the spammer is quite old, possibly a redneck who lived in his early days where coal supplied the heat. The word "soot" is certainly not confined to coal burning which can be affirmed in many places.
Finally I am amazed that billions are still being spent at Cern when there is so much division on the question of particles and waves and where the divisions between physicists
that have been unable to open discussion, where the physics leadership has declared it to be frozen to further discussion. Again a error in a check book does not correct itself overtime! An error stays an error until it is recognised and action taken.
If a formula is correct when using CGS units there is absolutely no good reason that formulas derived using standard units should not amount to the same conclusions thus forcing professors to take their heads out of the sand.
Best regards

David Platt made a comment on the subject of colour with reference to
who defines colour.
Animal eyes are different to human eyes in many ways including
physical distance apart.
angles of eyeball placement etc.
It doesn't hurt to think about what an eyeball is and its function.
A eyeball to my mind is nothing but a small FaradyCage that is
impinged upon by charge carrying particles where the impact is
transformed into a electric current so it may traverse the brain.
Their is really no way to descriminate the amount of filtering, prisms
and oils that is around with the species , or in the differences of
different brain abilities to decipher the character of different
colors. So I would imagine that some species can not identify the
color as humans see it and may not even discern color from black and
white. So nobody should take the step of assumption and making it a
fact.
Thanks to all you made the correscting comments
Art

That may be so, but my point is that if a person says that green is a primary color, it is not incorrect.

It isn't even a mmatter of wht other animals see, they can come up with their own color theory.

I use the different systems every day, from when I worked in a darkroom and used Cyan MAgenta yellow, to present day RGB for television and computer work, and CMYK for print. They work.

As for Art's theory, people assign colors, or funny names as a tool of understanding. The greenness or redness is only that, an electromagnetic oscillation at a frequency our eyes see as green.

Side note: there is no magenta in the spectrum, so there are some who are loathe to call it a primary color.

Were you aware that Maxwell gave a lecture to the Royal Society in
England on this very subject of primary colours? Presumably he was
persueing a connection with waves and particles or something like
that. As for electromagnetic oscillation at a given frequency, that is
beyond my pay grade, but I do have difficulty with discerning
differences between blue and green the same as the 10% of the
population!

Not when I was doing my fingerpaints in Kindergarten. When I wanted
green, I mixed blue and yellow. As you all attained your advanced
degrees, did you learn otherwise?

There are different ways to come up with colors, transmitted or
reflected. And the magic is that they will perform differently depending
on the mode.

You were actually using subtractive mode - Cyan-magenta-yellow. Your
blue and yellow combined and there you have it - green. Just like it was
supposed to.

Note that you color mixing fails at the lower and upper end. where the
color mixing won't be able to produce pure white or black. But for
colors in the middle of the range, it works well. That's why printers
use a cyan-magenta-yellow-and black model, with percentages rather than
steps.

We'll just ignore the anti-education zinger. Not sure what that's about.
This isn't rocket surgery.

A pure yellow and a pure blue would make black not green,
a pure red and a pure blue would also produce black.

I left my crayons at home so I can't try it.

Hi Jeff,

I went to your link above, and spent some time browsing. I came
across the statement you offer - and more:
>I have attempted to offer a total reassessment of the principles
>underlying color mixing. It is, I believe, the first major break away
>from the traditional and limited concepts that have caused artists
>and others who work with color so many problems.

.... Classic Unwin writing there = Buy my idea to find out how.

I have met with soooo many inventors to listen to their pitch for
venture capital, and like this example above, they all hedge their
presentation by obfuscating. To a man (or woman), they all perceive
that their "secret sauce" is too valuable to reveal.

It's been obvious to me since kindergarten that if I roll a ball on the floor, it comes to a stop all by itself. Then in high school them edjukated egg-heads tried to tell me it'll just keep going. No telling what them guys with advanced degrees must believe!

But I've been lookin' for the blue dots on my color TV, and couldn't find any. Musta been designed by one of them eggheads and not by a kindergarten pupil. Can't possibly work.

Oops, found the blue dots. But no yellow. So how can it make the
"primary" color yellow?

Good point. The author is selling a book. I wouldn't expect him to
disclose too many of his "discoveries" or one might not need to buy
the book.

I wouldn't exactly call it "classic Unwin writing". The difference is
that the author of the color book is intentionally creating confusion
so that the only solution for the reader is to purchase the book. This
is a common marketing ploy. A clear explanation would not require a
book to show how it works. A not so clear explanation does. Art has
the right idea, but isn't selling anything, so that's out. His style
of writing would be very useful, if he didn't over-do it. For example,
the right approach would be a long series of one-line comments that
everyone can agree with. Make it sound like a beginning of a logical
argument, but it can also just be some marginally related factoids.
After a series of generally agreed upon statements, drop in a dubious
factoid and immediately generate an "obvious" conclusion. If Art did
that, instead of starting with multiple dubious factoids, it would
probably be quite effective.

It's not really a new method. Cults and special interest groups have
been dealing with mysteries since the dawn of civilization. For
example:
<http://en.wikipedia.org/wiki/Mithraic_Mysteries>

2000 years ago, we would be debating the merits of how the various deities control antenna gain, VSWR, pattern, and propagation. The sales pitch today is similar. Spoon feed the GUM (great unwashed masses) with small portions of truth. When they become complacent, shovel manure down their gullible throats.

>I have met with soooo many inventors to listen to their pitch for
>venture capital, and like this example above, they all hedge their

Same here. In the late 1990's, I doing sanity checks on business plans for venture capitalists. Before handing someone a few million dollars, running a sanity check was considered useful. Much of the technology was little better than science fiction, but was so well written, that it was difficult to detect. Some even had patents. Gorgeous desktop publishing and graphics were great for gift wrapping. Even the serious ones tended to camouflage shaky areas under a cloud of technobabble and obfuscation.

Here's a classic:
<http://www.bizjournals.com/dallas/stories/2004/03/22/story5.html>
Patents: 6765479 and 5982276
Using a MASER to couple 2.4Gbits/sec to power lines for what's now called BPL (broadband power line) to the GUM.

Yep. See:
<http://www.greatreality.com/color/ColorMaxwell.htm>
He created the first color photograph using his idea of 3 primary
colors (red, blue, yellow) but without sensitivity to red or green.
Maxwell left a few unanswered questions about his method of color
photogrpahy:

Ok. Jeff. What did I do wrong? I am still being trashed because of my
statement.
I started off with the statement that if you add a time varying field
to a arbitrary Gaussian border containing static particles, in
equilibrium, then Maxwells laws for radiation was applicable. My
education was based around cgs units.
Every body stated at that point that it was incorrect, ala you can't
mix static particles with waves, or something like that. The group
never backed off from the position that the statement was in error and
the arguement and insults went on for a few months. Then a Phd from
MIT chimed in and stated I was correct and explained why. He also was
then trashed by all.
The group have not, as yet, moved away from that position.
What should I have done so as to continueing sharing my work since

denial of my statement stopped all necessary explanations ,as the statement was the discovery upon which antennas and radiation advancement was based upon. Note I was sharing my discovery not concealing it as Richard said.

The only antenna you have shown so far is just a warped up Yagi. This is nothing like you described"randomly placed full wavelength elements in equalibrium". The antenna you described is just a slightly messsed up Yagi with a slightly messed up radiation pattern. It seems like you should be able to learn from your own data that you havent done anything new.Why dont you model the antenna as you described it. Full wavelength radiators fed in phase and randomly placed"

Jimmie.

>So I can believe School of Color or my own lying eyes...

You can believe your eyes for two different cases of primary color - transmission (additive) and reflection (subtractive) - and one of those examples will say your eyes are lying.

Jeff's example can be tested quite simply (and was suggested by Roy). Take a displayed image (on your computer) of a photo of your swatch of your two colors, yellow and blue, mixed on a piece of paper in exactly the fashion of your kindergarten experience. Arrange it so the paper has yellow and blue margins merging into your green center.

As I said, display your art work on your monitor. Place a very strong magnifying glass near the display to observe the areas at the pixel level (I had to use 20X) You will find, true to your experience that the green pels of the display correspond to the green area of the mixed colors. You will find blue pels that correspond to the blue area of mixed colors. However, you will find no yellow pels in the yellow pigment you mixed with the blue - those pels are red and green. So, looking at the transmitted light of a reflected light image would have your eyes witnessing that there was absolutely no yellow in your original finger paint. The evidence available to your own eyes (and everyone else) would say that Red+Green+Blue=Green Do you believe that? It is your own yellow pigment that you took a picture of and examined on your own computer. Your eyes are lying to you.

Color is an illusion of the mind and nothing else but a convention of terminology.

It looks like a walk-in closet. The presence of the woman in the
towel suggests that a small shower may be behind her in the back, but,
otherwise I see no fittings for other needs, like a toilet, a stove, a
refrigerator, a bed, a chair. Except for the roof vent, light and
ventilation appear to be managed by opening the shell. Does fresh
polyester emit fumes?

Well, let's return to the claim:
>> A pure yellow and a pure blue would make black not green,
and examine the specifics "pure" yellow for instance and see where the
author leads us courtesy of amazon's "look inside" feature for this
book. Chapter three's title reads:
"Pure reds, yellows, and blues do not exist"

Makes it pretty difficult (and absurd) to test the author's claim when
that author pens an entire chapter in self-negation out of the box.

This is a classic Unwinism. (Compare Art's patent for a yagi that has
a reflector with a length shorter than resonance, and a director
length longer than resonance.)

>>Were you aware that Maxwell gave a lecture to the Royal Society in
>>England on this very subject of primary colours?

This has been beaten by an Englishman, Claude Friese-Greene, in 1927
with an additive system of only two colors: red and green. Note,
there is no blue, no yellow. I will quote a fuller description below.

For those who believe their eyes and the yellow of blond hair, and the
blue of the sky check out 5 seconds into:
Helmsdale, Scotland (1926) at youtube:
http://www.youtube.com/watch?v=dVy5gMTps3Q
There are also natural skin tones and reds too.

One can consider the blue of the Thames river in
The Thames opposite the Tower of London, London (1926)
http://www.youtube.com/watch?v=7BCfx651YQY

Then there is the classic
The Open Road London (1927)
http://www.youtube.com/watch?v=TwahIQz0o-M

Taken from Claude Friese-Greene's Colour Process
By BBC History:
http://www.bbc.co.uk/history/programmes/programme_archive/colour_process_03.shtml
>The film he used was panchromatic and so able to record colour in tones of black and
white. He also used a revolving colour filter wheel on the lens with one red filter, one
orange and the other clear.
>
>The processed film was then stained with red and green using a mechanical process on
alternate frames. It was then meant to be down to the viewer to effectively do the rest -
when projected at a fast enough speed, the eye plays a trick on the brain and creates the
illusion of a broader colour spectrum.

So, the primary colors your eye would believe come from
red/orange/green - something more suitable to Halloween than a colour
travelogue.

The original Technicolor (1916) was similar with an identical color
process (red and green) which had two separate color frames with
overlapping projection. Needless to say, the Technicolor we are used
to abandoned the first three versions of the two color methods to give
us the three color "The Adventures of Robin Hood."

I will repeat the cogent point about colour:
>the eye plays a trick on the brain and creates the illusion of a broader colour spectrum.

I bought the Sony XDR-F1HD and I really like it, no problem getting am 670 even with my crappy long wire installation, daytime signal is very clear. Haven't tried the nighttime signal but I'll probably need a loop as noted by others to get rid of the Latin station interference. The fm is very good also, good value for $75 or so. I'm looking at different options with the coax. It's routed around the perimeter of 3 walls then into another room and down a parallel wall before getting outside. I have 4 cheapo 8' fluorescent lights inside the 3 walled loop of coax and they create an annoying level of interference. I've confirmed the polarity and grounding on all the ac stuff so I'll write the hum off as noisy Chinese ballasts and leave the lights off. But anyway the move to the Sony tuner was a quantum gain. I have a tower from a conversion to satellite tv I'll erect this spring and install a fm directional and am loop antennas with a rotor. At that time I should be able to cut the coax down to a 20' run to the outside in metal conduit and buried another 20' to the tower in plastic conduit.

Roy,

I quite agree with you.

I have received a third hand comment that something in my related article at http://www.vk1od.net/transmissionline/stcm/index.htm is incorrect. I say something because there is a language translation involved in the third hand process.

Have you read the article, and have you any issue with it?

Thanks
Owen

Respectfully guys, Mixing colors like that doesn't give you black. And it's pointless telling Bill that his mixing of Yellow and blue didn't give him green.

If you place a dark blue gel in front of you, then place a dark yellow gel in front of that, it will certainly look black (though black isn't a color) But that's because all the frequencies are pretty well filtered out. That is what this guy who wrote that book is probably trying to say. That and a dollar gets ya a down payment on a cuppa at Starbucks.

Just as an experiment, Make three circles in a paint program. Each circle is on a different layer

Color one 255 red 0 green and blue.

The next 255 green, 0 others.

last one of 255 blue, 0 others.

So we now have three circles of the different primiary colors, the ones I learned about in 7th grade art class and have been using since the early 80's.

So we take the circles, and overlap them so that they cover each other in parts, yet leave most of their surface open.

Mike you idjit, they just cover each other up! SO let's try to make a transmission system on a solid piece of paper. Can be done, it can.

Make each color 50 percent transparent. There's a possibility you might need to arrange the layers a bit. sending one or the other to the back.

I did this, and viola! Got the red green and blue on the outside. they're looking a little pale, but they're the pure colors. Let's look in the overlap. Where blue and green overlap is a nice shade of cyan, blue and red is magenta, but what's this? Green and red is kinda brown!

This is a problem of the surface not being able to function exactly like transmission. But if you check your color tables, brown is just a darker version of yellow.

So we have the RGB, or the CYM primary colors.

He showed mathematically that I was correct. Theoretical physicists
use the cgs system of units the same as I was taught. When a book
along while ago decided to us SI units he made a mathematical error
which changed the whole concept of the law Because of plagarism all
school and college books now print this same error.

No it would not be on the market has I hold the patent and it is based
on the cgs standard
which is known to be correct

In this area, an Isotron would be a close example
> of what he thinks he has. But note that the builders of the
> Isotron do not proclaim it to have magical properties, nor
> do they try to explain it's operation using mumbo gumbo
> technobabble.

I have nev er claimed magical properties. When the cgs system is
applied to modern days antenna designs the results show higher
efficiencies in being sensitive to ALL SIGNALS

that arrive and where the same array needs a smaller volume than the yag and is not limited to a single polarity signal. In other words the computer programs are now proven to follow the laws of Maxwell where all forces are accounted for.

Even they seem to realize that the feedline
> is doing a large part of the radiating. :/

This has certainly been the case for many frauds foisted onto the ham community but it is not applicable to all arrays that differ from the Yagi and it is not applicablke in this case according to the accepted NEC programs

>
> The same could be said for directive arrays using cockeyed
> skewed angle radiators. If there was some magical property
> to these designs, they would already be on the market.

It would be great if they were as I would have a piece of that cake but I have not taken on any commercial deals.

> There has been some uses of swept back radiators in the
> past, but not quite the same thing as Art proposes.
> And they do not try to proclaim they break or ignore the
> rules of science.

Tis not I who is breaking the rules of science but academia in Universities and schools!

> Art gave one example of a skewed angle yagi months back.
> I modeled one in about 4 minutes using conventional
> yagi elements that handily beat his design in both gain
> and F/B ratio. His designs are inferior. :(

I and the others on the group would love to see a model of your sampling so this whole question of whether the NEC programs are in error as well as my judgement.
As an engineer I passed well beyond the point of junior high school so I take your limited education for what it is and try to decifer what you really mean. But you are so far off with your deductions that I can only assume the true reasons for your postings is insult and spam where the true use of this forum is to educate one self regarding amateur antennas.
Some may not agree with that format but free speech always rules.

There are links on the articles page to Hi-res photos of the dipoles and the location of their facility.

From the article...

Mr. Battis described the unique nature of the HAARP array, consisting of 180 transmitters distributed over 35 to 40 acres of land, with a frequency range of 2.65 to 10 megahertz.

<http://www.af.mil/news/story.asp?id=123193118>

Military scientists study ionosphere
by Bob Freeman
Special to American Forces Press Service

3/3/2010 - WASHINGTON (AFNS) -- At a facility in a remote part of south-central Alaska, the largest radio transmitter on Earth sends high-frequency signals into the ionosphere to help scientists better understand the influence of charged particles on radio communications and satellite surveillance systems.

Surprisingly, it also is able to create a mini-ionosphere.

"The High Frequency Active Auroral Research Program, a program known as HAARP, is basically a joint Air Force-Navy program to investigate ionospheric physics and radio science," explained James Battis, HAARP program manager at the Air Force Research Laboratory, during a Feb. 24 interview on Pentagon Web Radio's audio webcast "Armed with Science: Research and Applications for the Modern Military."

Mr. Battis was joined in the interview by Craig Selcher, HAARP program manager at the Naval Research Laboratory, and Todd Pedersen, a senior research physicist at AFRL.

"The ionosphere is a region of the upper atmosphere where there are a significant number of charged particles," Mr. Pedersen said. He explained that energy from the sun, particularly in the ultraviolet wavelengths, strikes atmospheric gas molecules and atoms with enough force to dislodge electrons. This results in a field of negatively charged electrons and positively charged atoms and molecules (ions), maintained in a plasma state, which conducts electrical currents and responds to electric and magnetic fields.

Mr. Battis mentioned that radio waves passing through the ionosphere are affected by the charged particles. "This can affect things like the quality of the signal from a satellite to the ground, or short-wave communications from ground to ground," he said.

He added that the signals from satellite-based surveillance and positioning systems also can be affected by the ionosphere.

"When the signals from GPS come down (from the satellite), their paths are actually deflected by the structure of the ionosphere," he said, "and some GPS errors are due

to distortions created by the ionosphere." He explained that while these errors may not be significant to the average user, they can be significant for precise military positioning. "That's one of the reasons (the Defense Department) is interested," he noted.

But the scientists all agreed that communications are the major reason for Defense Department interest.

"These are the transmissions which are used to communicate with aircraft and satellites, so the Air Force is interested largely in effects of the ionosphere on communications," Battis said.

Mr. Selcher agreed. "We have ships all over the globe that we want to be in contact with at all times, so any effect the ionosphere has on communications is something that we want to study," he said.

Mr. Battis noted that the research conducted by HAARP will benefit civilian communication systems as well, including those supporting civil aviation and ground communications.

"Satellite radio and satellite television can also be impacted by naturally occurring ionospheric conditions," Mr. Selcher added. "And trying to understand those is to begin to learn to predict, and maybe to (improve), the problem."

Mr. Battis described much of the previous ionospheric research as passive, with the evaluation of ionospheric effects based on the quality of reception of a normally transmitted radio signal.

"The radio waves we transmit from the array at our facility actively create processes and interactions with the particles in the ionosphere," he said. "Hopefully, we can learn what the responses are and how to use them to improve transmissions through the ionosphere."

"We have radio-wave sensors which send waves up to the ionosphere and listen for a reflection or an echo off something up there," Mr. Pedersen remarked. "And we have passive sensors that will listen to waves produced in the ionosphere, and also optical sensors."

Mr. Pedersen explained that when energy is directed at the ionosphere, some of it eventually comes back in the form of radio waves and some in the form of optical emissions.

"When these electrons get moved around by the electric field, they ultimately run into molecules up there, and when they have enough energy they'll become excited and give off light, just like the inside of a fluorescent light bulb," he said.

Mr. Battis and Mr. Selcher said that the radio waves emitted from the HAARP array create reactions that mimic natural processes in the ionosphere, but they are more controlled and their time and frequency input is measured, allowing the researchers to differentiate them from natural occurrences and better understand the processes at play.

"You can actually repeat the experiment again and again to verify that you're getting the right data and that the data means what you think it means," Mr. Selcher said.

Mr. Battis described the unique nature of the HAARP array, consisting of 180 transmitters distributed over 35 to 40 acres of land, with a frequency range of 2.65 to 10 megahertz.

"We can actually direct the signal within about 15 degrees of the zenith and move the signal in time," he said. "We can paint the sky. Similar facilities are typically restricted to three or four frequencies in that band, whereas we're able to do more continuous frequencies."

"That allows you to really expand the kind of experiments that you can do," Mr. Selcher added. "You can start sweeping the beam around in space, and you can change frequencies to determine if there's a frequency that has a stronger interaction with the ionosphere."

Mr. Pedersen described a surprising advance in the use of HAARP transmitters. He explained that at full power, HAARP is energetic enough that its signals not only light up the gas molecules, they're also able to knock additional electrons off, creating small areas of artificial plasma.

"Sunlight does that, and that's how we get the ionosphere in the first place," Mr. Pedersen said. "The aurora also does it. Electrons come shooting in from the aurora, from far out in space, hit the gas molecules, knock electrons off and create a temporary ionosphere for the duration of time the aurora is there," he explained.

In short, HAARP is able to create a small addition to the ionosphere. "We can add to the ionosphere enough that we can actually start doing experiments in that little spot of plasma that we created from the transmitter," Mr. Pedersen said.

Mr. Pedersen remarked that the next step was to figure out exactly what's happening in this artificial plasma and how to control it.

"This field has been data-starved for many, many years," Mr. Selcher noted, "because there weren't enough facilities that had the kind of power that HAARP has." He explained that theorists proposed many ideas to explain ionospheric interactions, but the data wasn't available to support them. HAARP is changing that.

"It's a nice position to be in as an experimentalist," he said.

There's plenty of detailed design information on HAARP available in the public literature. A bunch of technical papers on the antenna design and performance, the big transmitters (Eimac 10kW tetrodes) , how they control and phase it, etc.

google "HAARP IEEE" and you'll get plenty of hits. Most of the pubs are in the mid 90s.

not so much any more, getting too repetitious. time for something new now. this latest kick on cgs vs si is just a weird side show. all the good engineering texts show the constants converted to multiple units. for instance in Jackson they show the equations in Electrostatic units (esu), Electromagnetic units (emu), Gaussian, Heaviside-Lorentz, and Rationalized MKSA. The equations still represent the same things, only the constants are changed to confuse the uneducated... thats how we engineers tell who is who, by the units they choose and the direction of their current flow.

for instance, art chooses cgs, which is incomplete, much like his thought processes. and he probably thinks current flows from negative to positive, and he seems to prefer cartesian coordinates. That puts him firmly in the crackpot physicist zone. I prefer Gaussian units and positive to negative flow in cartesian coordinates which marks me as an electrical engineer educated in eletromagnetics... though i am also happy with rationalized mksa as used in ramo whinnery and van duzer's communcations electronics text.

I don't think I would have held back quite so much. He certainly
deserves anything you care to say to him.

I'll take what ever you've learned in school and since then, over what
Art, WHO IS NOT AN ELECTRICAL ENGINEER BY THE WAY, has to say about any
subject involving electrons and especially a subject dear to the hearts
of many here - Fields and Waves.

He is an idiot and a fool, and doesn't know anything about what he rants
about on this and other newsgroups.

I hope I was clear in my disapproval of Art (Im rite and EVEREE WON ELSE
IS RONG!) Unwin and everything he states. He is absolute proof that the
US patent system needs to be junked and rebuilt from scratch.

715. Which Coax (listening only) & Good Sources ?

Newsgroup: rec.radio.amateur.antenna

Hello,

Senior citizen that enjos HF and vhf/uhf listening, but frankly not very technical.

A few years back, I had to order some bnc, etc. connectors.
Ordered from supposedly popular source who said they had it all in stock, and had to wait weeks and weeks to get it as they obviously didn't. Would sure like to avoid that kind of experience again.

Do listening only.

So, please let me ask you folks:

for sma and bnc connectors, as well as preassembled (bnc or sma on the ends)short (3 ft or so) coax assemblies, who do you recommend as being reasonably priced (I'll use reasonably rather than cheap) and usually having in stock ?

For short lengths of coax, and listening only up thru the scanner freq's, what coax should I go for that would be inexpensive ?
RG 8x, RG 59, or...?) What to stay away from ?

Again, I need something "usable" up to about 1.5 GHZ or so, listening only.

Thanks,
Bob

For short lengths just about any coax. The RG-6 is very good if you have a way of crimping it to the connectors and do not move it very much. The shield is usually aluminum or some material that will not take solder. Goo d thing about that is you can pixk it up almost anywhere wire and cable is sold.

Up to about 50 mhz any coax about 1/4 inch (rg 58 /rg 59 size) or larger is fine. As you go above 100 mhz, the larger the size the beter. It just depends on how large you want to go and how much you want to spend.

Use 75 ohm Cable TV coax (RG-6 and similar).. All you'll need to buy
that's at all unusual is appropriate F:whatever adapters for each end.
The foam dielectric coax is low loss, will have male F connectors
already on it in a variety of lengths, etc. Available everywhere.

For the adapters, try Mouser, Digikey, Newark, or Allied for regular
mailorder, or perhaps something like L-com or Pasternak for a more
specialty, or the various surplus places. BNC M to F Female run about
$2 from L-com. Radio Shack carries some adapters, but in-store stock is
variable.

For a receive application, the small impedance mismatch probably won't
be a big deal, unless you're looking for the last tenth of a dB of noise
figure.

718. Turn an FM Transmitter into a Micro Pirate Radio

Newsgroup: rec.radio.amateur.antenna

Corporate radio is preprogrammed junk. But don’t curse the DJ; seize the airwaves!

With a soldering iron and a cheapo FM transmitter — the kind used to play an iPod through a car radio — you can transform your humble Honda into a Radio Free Civic that can broadcast your tunes up to ... 100 feet.

Step 1. Pry open the transmitter’s case with a putty knife and remove the internal antenna
(often labeled ant).
Step 2. In its place, solder a telescoping antenna or a piece of copper wire — no more than
35 inches long for broadcasting within the standard FM transmission spectrum.
Step 3. The transmitter may have a resistor, typically marked with an r, to limit the power of
the signal. Replace it with copper wire to boost the transmission.
Step 4. Slap a bumper sticker on your ride advertising your station’s frequency.

You’ll soon build a grateful audience of fellow commuters suffering through that traffic jam.

I would like to improve my little FM transmitter to broadcast my playlist music from my Zune. Got extra advice?

Message-ID: <f895b32c-a49b-4d09-b686-440300ec202b@g19g2000yqe.googlegroups.com>
Source record: 10721

My latest antenna is up!
It is a window mesh curtain 8 foot by 100 foot
about 1 foot off the ground.
It is an all bander with the xmitter tuner on all the time,
later I will trim it so I can leave the internal tuner off.
At the moment the red light comes on when I am right in the center
only
of the top band and the SWR reads 1.5 for the middle section only!.
Presume the tuner cannot handle above 1.5 on top band.
Very, very quiet antenna, but it has been up less than 24 hours.
Feed is on one side only with the ground connection about 2 inches
away
on the same side with the connections at the bottom some what towards
the center of the curtain length ways.Basically it is a long one wall
Faraday shield but without a drain ground on the front side.
Will find a relay so I can make it bi directional

So he is center feeding a large curtain with a "_2 inch_" wide feed.

Yup, that WILL very definitely be quiet. I hope the tuner has a lot of loss in the way before the "antenna" (chortle) to dissipate the 99.999% of the power fed to the short at the end.

> Basically it is a long one wall
> Faraday shield but without a drain ground on the front side.

It's not a Faraday shield if it's not completely surrounding something. I'd suggest a smaller one. Of tinfoil. Around your head. It won't help, but it would be amusing.

Source record: 10727

Hi,

Just a bit of a followup from my previous post.
Am in my 70's now, and not too sharp with this stuff anymore.
But, I really enjoy sw listening.

Doing some re-plumbing.

The suggestion was made that the common RG-6 that is everywhere would do
me just fine, as I'm talking about about 3 foot patch cord lengths.

Listening only; mainly the scanner vhf/uhf frequencies.
And possibly on occasion up to about 1.5 GHz, at most.

Everyone has them,from Wal-Mart on up

The RCA branded cables seem to be most popular.

Probably a very cheap implementation.

Think this would do me O.K. as the lengths are only 3 feet, and
listening only ?
Or, too cheaply made probably, and I should try to find somewhere a
better quality ?

They all use these F connectors.
Guess I'm old fashioned, but they "scare" me a little not having a
"real" center pin.

Any reluctance to using them ?

Thanks again,
Bob

They'll do you fine, Bob. In fact, if the center conductor isn't nicked during construction of the connector, your going right to the conductor, less in between stuff to fail.

Now that isn't a really big point, because RF connectors are a pretty reliable lot. But there is nothing wrong with the F connectors except for they're small, and I have big hands. SMA are better quality, but you're in good shape with the F's.

A Faraday shield allows for magnetic and elerctrical fields to
separate and cancell leaving a RF current thast radios are designed to
handle. The shield unlike what we view as radiators has two side that
are independent of each other where as a "normal" radiators surface is
not separated electrically. The Faraday shield operates at 90 degrees
to an oncomming signal by a blocking method and does not operate as a
recieving type surface
that is directly connected to a radio. The Faraday shield as a single
wall still has a blocking action as fields can encircle the wall but
it cannot protect all. It does however protect the rear surface from
field impingement and the field usually will connefct to a alternate
surface leaving a void directly behind the shielding wall.
The Faraday shield on the other hand is an enclosure that shields the
inside from encroachment on the outside such thast fields do not
interfere with activities within. It does not perform the function of
field separation. In most radio circuits you will see examples of bot
enclosures and shields where the latter incorporates physically
unconnected surfaces for electricaly closed loops.
I don't mind your postings Tom as it provides those that are educated
some idea of your true standing in life.
With respect to a closely aligned feed which to your mind leaves an

imediate short;.
I suggest you look at a three band dipole all connected at the same point. Each dipole provides a low resistance path for a particular applied frequency in its seach for a closed circuit. The applied current will not divert to a path of higher resistance or impedance in this case because we have to consider the effect of phase differences. With these sort of actions we can have several different paths for the current to follow but I assure you that it will pick the same one every time dependent on the frequency applied.
Now to the wire mesh curtain. It provides a separate low impedence path for every frequency applied to it as well as a separate path for the displacement current that encloses a separate field (see my page) which has the abilitity to accellerate mass as with an electric gun.The maximum accelleration applied to mass is obviously determined by its intrinsic mass where a minimum mass determines the speed of light. Today the smallest particle found is that of a Neutrino thus one can see the connection of the Sun to communication as we see it today.
Regarding your description of the shield to a long wire or dipole, gthe curtain or shield does not provide a electrical connection for both sides of the shield as a dipole or long wire does.
See Tom, your past postings are completely devoid of technical content and probably provide all readers with a silent chucklel
By the way, a curtain is able to supply a very large aperture which is synonimous with the amount of gain it supplies. You might want to ponder on that aspect before you disparage it.
The above is provided for you and your friends to salivate apon so you may provide a few more chuckles to those on the side lines.
Note I have left some grammerr and spelling errors for you to comment upon in the absence of any technical content.
Cheers and beers

Hi Bob,

Then RG-174 would work just as well - if you wanted something very
thin and flexible.

However, the common application of the term "patch cord" is a short
connector to a variety of very much longer transmission lines. If
that is the sense of "patch cord" that you mean, then your longer
lines, for your range of frequencies, should be very large diameter
cables. There the impedance doesn't really matter that much - so go
for biggest/cheapest.

>Think this would do me O.K. as the lengths are only 3 feet, and
>listening only ?

OK, so this is twice you have mentioned the 3 foot criteria. And you
have mentioned lengthS (not length) as though you need many.

Two questions arise:
1. Why do you need many?
B. How far away is/are your antenna/s?

>Or, too cheaply made probably, and I should try to find somewhere a
>better quality ?

You haven't described any problems that demand quality.

>They all use these F connectors.

They usually get by quite well under normal circumstances with them.
As you have not described any abnormal circumstances, you would get by
quite well with them too.

>Guess I'm old fashioned, but they "scare" me a little not having a
>"real" center pin.

Close your eyes, take a deep breath, calmly insert and tighten the
fittings.

>Any reluctance to using them ?

Not when they are appropriate.

Hi Dick, et al,

Thanks for help.

Sorry I wasn't too clear.

I have an outside receive only aerial for my HF that is probably 50 feet
from the room where I do my listening.
Also a Scantenna for my scanner up in the attic, overhead..

Getting a WinRadio G305. (has HF and vhf/uhf capability)

So the 3 foot, or so, lengths are just some simple plumbinmg in the room
between the ends of the present antenna lead ins, and two A/B switches
to switch the antennas between the present receivers and the new WinRadio.

No room to provide everything with their own antennas, so trying to do
it with A/B switches.

Regards,
Bob

I don't see any probem with the F connectors. There are millions of them
used in cable TV and other TV applications. They are cheap enough that if
you leave the coax long you can just cut the end off and install another in
a short period of time.

No, that's absolutely incorrect. Nothing is separated. And what's left over, if anything measurable is, is an electromagnetic wave.

> The shield unlike what we view as radiators has two side that

And I'll just summarize all the last part, since it would be a total
waste of time to comment individually on points -

YOU ARE WRONG. Totally, completely, and terribly wrong.

And no, I'm not going into how or why, because you never ever listen or
understand.

Oh My. I am wrong but you are unable to describe how I am wrong,how
convenient!
You need to brush up on attenuation versus skin depth, surface
conduction and a host of other things such as a sealed surface can be
considered as an aperture with respect to shielding. I would recommend
a book on shielding etc by Ralph Morrison 5 th edition that will bring
you up to date on the function of perforated shielding plates,
screening etc.Just saying that I am wrong without explanation or
explaining your record on the subject is nothing more than the voice
of a child exercising free speech.If you can provide technical data to
support your position we can discuss but just saying one is wrong
serves nobody.
One thing you really need to understand is the nature of a
accellerated and decellerated charge and its connection with a time

varient current, the latter being the only connection
that a xmitter or rcvr can handle to provide communication and its
connection with a parallel tank circuit.

Have a happy day
Art

If you were to supply a sufficient description of what you have done,
you might to get more detailed responses. For example, it is unclear how
you have connected the feed line to the mesh. A photo (you have a
website, you could post it there) would make the details much clearer.
You have not specified the nature of the mesh (the material, the
thickness of the wire (assuming it is wire), how the intersections are
joined, etc.). The orientation of the mesh relative to the ground is not
specified.

You seem to expect detailed responses without out providing any details
on your part.

Just believing you are right without providing any details does not mean
we have to accept what you say.

If you can provide technical data to
> support your position we can discuss but just saying one is wrong
> serves nobody.

Where are the technical details to support what you are syaing about
this antenna? Frequency of operation: unspecified. Performace relative
to known/understood reference antennas: unspecified. Feedpoint
impedance: unspecified. Test conditions/setup: unspecified.

You have failed to show how a parallel tank circuit applies.

739. Parallel tank circuit

Newsgroup: rec.radio.amateur.antenna
Date: 2010-03-11 16:28:44 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <9a05c1b1-776f-4af9-b983-d4f08d891999@q15g2000yqj.googlegroups.com>
Source record: 10739

A tank circuit represents an antenna closed circuit where in the
absence of friction shows the action of electric field changing to a
magnetic field as a sample of perpetual motion. However perpetual
motion does not exist so to account for all forces involved we have to
determine the amount of friction. We cannot use a series circuit as we
have no way of determining friction OR the point of the curve crossing
the the zero reactance level.
Thus we have to use a parallel circuit where we can use the cross over
point as being a period where it is seen as balanced and in
equilibrium.
The reason we cannot use a series circuit or anything pertaining to a
fractional wave in examining the performance of a radiator is because
the impedance curve does not represent a true sine wave. After a
period of time has occurred the source replaces any frictional losses
that have occurred. To do this the amplitude of the curve at the
beginning of a cycle moves higher than any othe point on the curve
where it replaces and exceeds the frictional losses that have
occurred. By doing this it uses time that is not in accordance to a
true sine wave and detracts from the accuracy of the following curve.
This useage of time during a period or cycle must be accounted for if
one is to determine all forces involved, which is why equilibrium or
balance must be followed when determining the characteristics of
radiation. There fore ,it should be seen that a full wave length or
multiples there of should be considered when dealing with radiators
since otherwise we are ignoring the overshoot effect required to
replace frictional losses.
Modern computer programs equiped with an optimiser are equiped to deal
with this as they will modify any inputs such that they are in
accordance with Maxwells laws where all forces are considered.
In the case of a yagi it must be seen that each element radiates
including the last one where the value is unknown and not included in
a fudged result. If one supplies an input that does not pre guide a
planar solution all optimiser programs will account for all forces
involved and will always supply an array that is not planar as a yagi
shows.
Thus for accurracy with respect to Maxwells laws one must have an
array that is in equilibrium which reflects Newtons laws where vectors
outside the "boundary" such as gravity and the Earths rotatation is
reflected by opposing vectors within the boundary. The consequences of
this is that the rotation vector in combination of that of gravity
will always produce an array that opposes gravity alone as with a
vertical at 90 degrees to the Earths surface if one pursuit is
accuracy.
The requirement of equilibrium is shown by the law of Gauss which when

added by a time varying field equates to the laws of Maxwell which demands the presence of equilibrium and shows that a static particle must be present to provide mass to which, via accelleration or decelleration, which serves as the carrier of charge or charge. This in no way conflicts with ideas or theories that particles and waves can provide similar properties under certain cercumstances but instead provides proof that particles are the carriers of what is known as communication.
Cheers and beers.

joe
I'm with joe,
Some of us may be interested enough to actually build and test some
of the antennas you write about, but there is never enough detail for
anyone to attempt a build. And why don't you post a link to your site?
Mike

If Maxwell and Gauss building on the observations of Newton
postulated that particles were the carriers of charge fpr
communication it is essential that we determiune where the particle of
mass came from together with its properties.
For consistencies sake we will continue with what boundary laws leads
us to.
Obviously the particle was initially with in a boundary when the
boundary was broken.
Since the Sun shows that it has a connection with communication let us
assume that It is the Sun inside the boundary or something else within
that boundary. If the boundary is to be broken mass is to escape. This
it can do by applying a vector on the boundary that removes
equilibrium. At the same time as the mass proceeds thro the hinged
breakage another vector is created on the escaping particle which
imparts spin. It is these same two vectors that are at the end of a
long chain of vectors which are those of gravity and the Earths
rotation. It is known that each cubic metre of volume of air on Earth
contains billions of particles that arrive from outer space where they
look for a place to rest. Most of the Earth is covered by diamagnetic
materials or surface and we can see the effect of these particles that
provide a skin upon diamagnetic surface such as water, aluminum. These
particles squeeze themselves together such that they can form water
into droplets where the particles are strong enough to completely
encapsulate the water or most liquides that
do not retain the effects of magnetism.
We make our antennas of diamagnetic materials where the surface is
completely covered with the smallest particles known to man.
Application of a time varying field applies vector forces upon the
material surface where these vectors are three dimensional form such
that they can elevate and eject these particles in a accellerated
manner so they may carry a charge (see my page for current flow
diag). The particles being the smallest known mass
represents the highest acceleration possible and where it happens to
be equal to the speed of light.
It must be noted that a radio can only apply a time varying current to
a radiator which has a pre determined speed in metal so that the
period or cycle can be determined. This speed in metal becomes very
important when dealing with creation of fields and the impact of this

particle on materials where the penetration of such particles can attenuate the charge that it carries such that it can lose 3 db of charge for a penetration oif one skin depth and continues in parabolic form when it produces a vortex.
The two vectors or forces shown show why Einstein considered a standard model was possible in the same way humans follow a genetic code. Einstein eventually was able to determine the presense of particles by another method or physic science. For those familiar with the double slit experiment depth penetration or surface encapsulation of
orifices were never taken into consideration so the conclusions cannot be seen as complete. Hopefully this satifies the request where allsqlient particulars are supplied other than whether a, b.c.or d should be marked in the event of an exam.

Hi All,

This is not going to resolve issues. I have seen enough of Art's
details contributed in quotations (folks should be more selective in
both quotes and focus on one point) to see he claims ALL of HF at less
than 2:1 and specifically the 160M band - when he uses a tuner
continuously (an odd requirement adorning the claim in the advance
over conventional designs there). He also reports not hearing
anything on it. The two statements easily support each other in
revealing the inordinate loss due to the proximity of ground. This is
nothing that hasn't been reported for years by others as they
encounter the silent blessings of distributed loss.

The language of Faraday shields has been corrupted to suit a fantasy,
however. And Art has abandoned the arguments demanding length
efficiency; and no requirement for tilting the radiator (this one is
specifically described as being strictly parallel); and skewed
elements (aka guss's radiators)are gone; and contra wound coils have
disappeared; and what happened to paramagnetics?; and....

Well, Art's claims are like a long burning fuse that sparks for a
moment leaving a trail of ash behind. The mesh burns with a
sputtering flicker before it too is abandoned for the next fad when it
will be discovered that the sun's particels would go through the mesh
openings instead of hitting this peculiar antenna.

Computer programs for antenna design are really one of two forms.
The cheap versions are the most prolific as they are designed to show
the properties of planar arrays. These array are generally in the form
for dealing with wire and Yagi antennas
which is the vogue of the day and what customers want.
These reflect the principles evoked by Yagi and Uda which provides an
array of very high efficiency and uses standard electrical laws where
provided figures are those that are rounded off as all vector forces
are not taken into account. At the same time amateurs recognise that
even if the figures provided were absolute would not be discernable by
the human ear, so we have a "close enough for horse shoes" effect.
The other type of computor program is much mor expensive as it deals
with basic physics
where accuracy and truth is important so one can build upon it. These
programs are based solely on the laws of Maxwell which when modified
in line with later discoveries were built on the observations of
Newton. These programs will take any dimensional input and then place
it into a equilibrium state according to the laws of Maxwell because
it accounts for all forces is accurate. It is usual for programers to
apply additional lines in the program that deviate from Maxwells
equations for radiation so that it may accommodate planar designs such
as the planar designs which, while using standard electrical laws,
cannot handle all the forces involved in radiation.
The important difference between these two types of programs is that
the the optimizer form is so accurate it can supply figures that
account for radiators with zero resistance which effectively leaves
just the radiation resistance. This is where the radiator is doing
nothing to provide radiation and only supplies a space for particle to
settle upon. It is these particles that are the carriers of charge

that are elevated and accelerated by the time varying current so the results represent the maximum radiation possible when the element is a super conductor with zero resistance. Hams have to deal with the real world realise that when applying current one must have a semblance of match thus even tho we desire maximum efficiency it is the facts pertaining to matching the source with the radiator with minimum losses that guides us to something that we can effectively use.
Cheers and beers

I can concur. I won't go so far as to say they won't "work" - whatever work is defined as, but I don't see any new ground being broken.

ANother of Art's antennas, the rotatable coil on a stick is a tuned circuit on a stick, and probably functions as a EH antenna. I'd guess that most of it's radiation would be from the coax. Looking at the instructions given, I figured that's what it was going to do, so didn't take it any further.

This mesh device is either a wide dipole or a somethingorother worked against ground. It will probably tune and put out a signal. I wonder how things will work as it corrodes? Might get complex.

If you need to use a tuner, you might as well just put up as much number 12 THHN wire, and tune it. My doublet with an MFJ tuner works great.

Guys, I can't explain the antenna if you do not accept the basic
premise of adding a time varying field to the law of Gauss is the same
as Maxwells law for radiation. All of you state it is a false premise
which means nothing is acceptable! For my part I am dealing with known
laws of physics only which is what you are rejecting.Ask any body such
as a professor or anybody who teaches theoretic physics for an
opinion. At the same time find out what Gauss equation in cgs units
changes to when you add a time varying field!

To me it is obvious that as the old timers pass on they are being replaced by operators of a hand mike who have absolutely no interest in experimentation,how a radio works or the physics background of same. Having one of the new licenses to hold a microphone does not make one an expert of any sort let alone a major in physics. Nobody but nobody has ventured forth the resulting equation or proffered anything to justify allegations of radiation from the feed line or any other scientific fact in rebuttal to what I propose. So based on your postings I can only consider you to be microphone holders with absolutely no interest in physics and only interested in the straw men that you manufacture based on untruths to which you base your arguements upon. Frankly none of you can handle the truth or change from the past. I suppose this particular thread has now come to an end as your understanding of physics results in different result from mine and you now prefer to supply insults or spamming in line with your fellow poster KB9QRZ who now appears to be using different calls to attack to hide his identity based on the content of the posts.
Cheers and beers

The laws of physics were not questioned. I just wanted to know how you
made the antenna. You are evading the issue.

> To me it is obvious that as the old timers pass on they are being

You nailed it. Your understanding of physics differs from mine. It also differs from any physics professor you would care to speak to, which is why none have shown up to support your nonsense. And differs from everyone here that has designed (that is an important word) an antenna that works as predicted. With real testable numbers and all that silly stuff.

Interesting that Art hasn't the slightest idea how the programs work.

Of course most know that the programs don't know or care about orientation.

Most also know that the optimizers only look at what figures of merit
that you tell them to.

I'm sure his supporters are really cheering now.

In a lossy coax the lost energy is, I suppose, heating up the dielectric.
To try to visualize that I stripped off 30 cm of dielectric from an old RG58 cable and put it in a 900 W 2450 MHz standard microwave oven together with a 100cc cup of water as dummy load.
2 minutes after switching on the water was boiling but the polyethylene was only slightly warmer due to the proximity to the boiling water., Can I conclude that RG58 dielectric has no loss at 2350 MHz ?
Certainly not (it is well known that all the PE food containers used in such ovens are not heated), but what is wrong in this test ? how does it differ from the dielectric heated in an actual operating lossy cable ?

there is more than dielectric heating. there is also heating in the
resistance of the conductors and leakage from incomplete shielding.

Up to very high frequencies the major loss in coax is in wire. The skin effect makes the center conductor effective wire diameter much smaller than what it is at DC. The higher the frequency the more loss in the wire due to the skin effect. The reason for some types of coax of the same diameter have less loss is not because of the loss in the dielectric, but because it lets the center conductor be a larger diameter for the same shield diameter. Not much is lost in the dielectric. The other major loss is in the shield and it is lost the same as in the center conductor.

The loss of such cable is rated in dB per 100 feet. Your 30cm
(roughly a foot) is a substantial fraction. If we were to perform a
first order estimation from that alone; then by consulting the charts
for RG58 at 2450 MHz, Times-Microwave doesn't even go that high.
Instead, taking their 1GHz figure of 15.3dB and abstracting that to
20dB and then taking its fraction for your length, then we get
something on the order of 0.2dB.

This would be roughly a 5% load to your 900 W IF that power were
confined to the cross-section of polyethelyne in TEM mode. It is not.

If it were, that would have 45W spread across 30cm. Think of that
length as a series of 30 half-watt resistors. That would have each
resistor over-taxed, trying to dissipate 1.5W each. Now, take one of
those resistors between your forefinger and thumb. How hot is that?

Depends on the frequency.

At lower (HF and VHF) frequencies, the loss is coax is dominated by
resistive losses in the conductors. The RF current is flowing through
copper (which has a non-zero resistance per foot), and isn't even
flowing through *all* of the conductor (the "skin effect" constrains
the current to flow through a thin layer on the surface of each
conductor).

The current flow through the resistive copper creates a voltage drop,
and dissipates power... which then heats up the conductors. The
dielectric and outer insulation are also heated, but indirectly...
heat flows into the warmed-up conductors.

There are direct losses in the dielectric (in addition to the
resistive losses in the conductors) but as I recall these don't become
significant until you're well up into the microwave regions.

>Certainly not (it is well known that all the PE food containers used in
>such ovens are not heated), but what is wrong in this test ? how does it
>differ from the dielectric heated in an actual operating lossy cable ?

Your test omits the indirect heating of the dielectric, from
conductors which are themselves heated by resistive losses.

Others have set you straight about most of the loss being due to heating the conductors (I^2*R loss) rather than dielectric loss. Look in the thread "Two coax as substitute for open line" thread for my posting on 25 February; it contains a formula for line loss that lets you see how the two loss mechanisms stack up as a function of impedance, frequency, conductor size and dielectric loss tangent.

An interesting point to note: If you buy line of a certain impedance and diameter, you'll note that if the line uses solid polyethylene dielectric its loss is higher than line of otherwise the same construction using foam polyethylene dielectric. The reason for that is NOT that the foam dielectric is less lossy, but rather that the lower effective relative dielectric constant of the foam requires a larger diameter center conductor to get the same impedance, and the larger center conductor has lower loss.

If you assume copper conductors and dielectric with a dissipation factor of 0.0002 (which should be close to what either polyethylene or PTFE of high quality is, up to a few GHz), you'll find that RG-213 size coax with a 0.285" outer conductor ID and solid 0.081" inner conductor (appropriate for solid polyethylene 50 ohm line) yields the following _approximate_ losses, in dB/100ft:

	Total	Copper	Dielectric
1MHz	0.138	0.137	0.001
10MHz	0.437	0.433	0.004
100MHz	1.383	1.370	0.013
200MHz	1.957	1.938	0.018
500MHz	3.094	3.064	0.030
1GHz	4.376	4.334	0.042
2GHz	6.188	6.129	0.059
5GHz	9.784	9.690	0.094

You can see that even at 5GHz, the dielectric loss in this particular line is quite small compared with the copper loss. It would be appropriate to use a bit higher dielectric dissipation factor in the GHz region, but even if it's ten times as large as what I used here, the dielectric loss is less than 10% of the total, at 5GHz. The calculation I used here is idealized, but the non-idealities tend to be unrelated to dielectric loss: things like conductors that aren't smooth copper (braid; stranded center conductor) and small variations in impedance along the line that cause additional apparent and real losses. It does depend on the dielectric not becoming "contaminated," but modern cable construction seems to do a good job minimizing that, if you use the cable in reasonable environments.

Cheers,
Tom

Oh, crap. Let's try that again. I looked at the table above and it did NOT look right. Wondered why the ratio of copper to dielectric loss didn't get worse with increasing frequency. Made a mistake in the spreadsheet that calculated it. Should have spotted it before I posted it. This is probably better:

Total Copper Dielectric
1MHz 0.138 0.137 0.001
10MHz 0.442 0.433 0.008
100MHz 1.454 1.370 0.084
200MHz 2.105 1.938 0.167
500MHz 3.482 3.064 0.418
1GHz 5.169 4.334 0.836
2GHz 7.800 6.129 1.671
5GHz 13.869 9.690 4.179

So the contribution of dielectric loss by the time you get to 5GHz is significant, but not dominant if the dielectric is high quality and uncontaminated.

Earlier we stated that the present planar designs such as a yagi were quite efficient so why should we bother with understanding designes provided by optimiser according to Maxwell? First of all it provides an understanding of radiation which has eluded us for more than one hundred years. It also shows when pursueing this line of logic of maintaining equilibrium it tells us that we can compress a radiator to a smaller volume. In addition we can add that Maxwell only uses distributed loads therefore one must cancel any lumped loads that are added in construction.(very relavent with respect to the Kraus helical design)

It also prevails upon us to determine efficiencies of one antenna design compared to the other!
When considering radiation we must be aware that dependent on the design of a antenna array controls what incoming signals it is sensitive to use for communication. Planar designs are usually designed upon a single polarity and not so much as supplying sensitivity to other polarities, where as designs based upon optimiser versions are made
sensitive to all types of polarity such that useable incoming signals for communication climbs up
several 100 percent. Since by definition maximum radiation efficiency occurs when the current does not penetrate the radiator surface(zero element resdstance it behooves us to look at plate forms of radiators which points to the function of a Faraday enclosure or shield or even a metal mesh where the perforations are controlled in size relative to skin depth. These same perforations provide a path for displacement current and eddies that provide for elevation and acceleration of charge carrying particles, in the case of transmission, where the vortex contains a field that is intersected by a field at right angles

from the radiator where the acceleration of the particle is supplied. It should not go with out notice that for a particle to attain the highest velocity possible it must be of the smallest mass known which as the present time is a neutrino which, by definition, is the same as the speed of light and where in its earlier form as Leptons came from within the boundaries of the Sun where it deposited its accumulated charge to the Earths boundary upon entry and its search for a diamagnetic surface to rest upon.,
So here we are with a new theory with respect to radiation which is in agreement with existing known laws of the masters, which is recognised and affirmed by present day computer programs that are dependent only on accepted laws and where they mesh with the above stated theory. In addition, it provides support for Einstein's leanings on the Standard Model and that Maxwell's laws on radiation would prove to be the final link. All was not lost for Einstein as he later focused on other strains of physics view points which then supported his position of particles being the carriers of charge in communication and NOT that of waves

Art (N.B. please) ...

The POLARITY of an electromagnetic wave is determined by its electric field vector, which reverses direction (polarity) every 180 degrees of the waveform -- regardless of the polarization of the wave.

The POLARIZATION of an electromagnetic wave is defined by the physical orientation of its electric field vector, regardless of the polarity of that field. For linear radiators such as a dipole and monopole, the direction of polarization is that of the physical orientation of the radiator.

So although these terms rather sound the same, they aren't synonymous.

The applet linked below is useful to visualize this. To see vertical polarization, first set the Ey field to zero, and start the animation (top center of the page). Then set the Ex field to zero and the Ey field to one to see horizontal polarization. The blue lines tending to fill in the a-c waveform represent the field vectors of the radiated wave.

In this applet if the Ex and Ey fields are set to equal values (say at 1 each), and their phase relationship to -90 degrees using the slider below the Ex and Ey sliders in the Input Section of the applet, then the resulting e-m field is perfect, right-hand circular polarization. The animation shows a net field vector of constant magnitude rotating through all polarization angles once per wavelength.

Also note that the perfect, c-pol field shown in the applet is the net field of two, linearly-polarized radiators when configured as described above.

don't confuse him with the facts! that just shortens the threads, keep trying to get him to explain his new theory so we all have something to laugh about. yucky freezing rain here today so need something funny to keep my mind off how my nice planar yagi's are turning into art's non-planer twisted designs all by themselves.

Based on his "designs", which don't seem to exist except as whimsical nonsense, I would wager large amounts of cash that you couldn't possibly have a QSO with him.

Figure 22 of http://www.qsl.net/i0jx/ros.html separately shows loss caused by copper (in red) and loss caused by dielectric (in blue) for a 100-meter run (about 330 feet) of LMR-400 coax (similar to RG-213 with foam dielectric) versus frequency.

The formulas used for the plot are shown just above it.

Though it is in italian, it should be easily understandable.

Aaarrrttt!! Where are you?

Let's have a nice QSO with you using you wondertenna.

Of course we will never know how it really works since you'll have to
use a conventional antenna for the QSO because your wondertenna radiates
like a dummy load.

Front to REAR would appear to be equal
or better than a dish!
Makes for a very quiet receiving antenna as well as being very good
for transmitting
basing gain on aperture. Very easy to reverse direction using a spst
relay.

774. Alliance Tenna-Rotor for sale

Newsgroup: rec.radio.amateur.antenna

Had an E mail asking questions about the antenna not wanting to post on the group!
My meshg curtain moves away from the other antennas that I have made with window mesh which are designed for tower top with a rotor. The curtain I have made is much bigger than required but with commercial statiions using curtain style antennas I thought I would make one out of interest. I used all the mesh I had accumulated which amounted to a 100 yards by eight feet stapled together and hung it up just like the washing line of the old days so it wasn't touching the ground. Both sided are grounded and you must view the array as two separate sides where with the use of a spst relay you connect to both sides with the coax and switch out the side that you are using as a reflector or vica versa. The ground I used was just a stake in the ground. The swr span is dependent on the size of the curtain and I wouldn't be surprized if the amount of wire in the mesh has something to do with it. The Swr on my curtain is less than 2:1 up from the top band on all frequencies. I have a AM station in sight close by which normally is some 20 plus over nine. My reflector put it to some where below 5 S units a very rough observation.
Books usually refer to the use of chicken wire but my mesh is 20 by 18 per inch and aluminum! i am assuming that current views it as a surface or flat plate so the current disperses. The wire is coiated with a type of nickel or conductive coating so I dont remove the coating any more. The aluminum wire is woven so I roll it flat so that good contact is made.
You can connect the coax any where but make sure you are not penetrating to the other side. You can actually put the coax centre wire just an inch or so from the ground connection and no it will not short across. All ground connections must be to the same point. The wire mesh is a two sided antenna where the edges of the curtain being quite sharp provides a barrier to prevent cross over. The antenna is really just a Faraday shield where incomming signals hit on the side which is facing the signal. Now first the static is removed and channelled to the ground. The actual signal hits the side like a

sticky particle and separates into two fields electric and magnetic. One field stays stuck to the outside and the other side gathers the other field (I won't go into how the other sticky particle gets to the other side but it comes from the Laws of Newton).
The inside particle then wants to slide over so it is opposite the position of the other partical
or field. We know that radiation is created by an accelleration of charge so going backwards in thought the insiden moving particle or charge created provided a time varing current wbhich the radio can handle. Getting back to the two particles or field these are now equal and opposite and thus will cancel. Thinking a bit more about it, the current produced a electric field which turned into a magnetic field and then back into a electric field just like it would with a parallel tank circuit so when the fields cancelled you only have left the applied current!
Remember now that we have always looked at radiators as wires but in this case we are viewing our radiators as a solid plate though we do have very small holes in the surface where the impinginging particle cannot get through beyond what we call skin depth.
Remember also that the charge carrying particle (not a wave) also has a spin to it like a bullet so it can maintain a straight line together with a cancellation of gravity, so the particle must be viewed as the smallest mass possible BUT WITH A ROTATION OR SPIN that has a radius in excess of the holes size. So really the radiator doesn't totally block a signal like a mirror but it does absorb the signal depending on its thichnes ie one skin dept penetration equals three db attenuation etc.
Explanation is a bit long but for those who are not willing to get involved but are still interested I am hoping that this will help.
Bottom line is that if you add a time varying field to a Gaussian static boundary you then have the same formula as Maxwell. Thus waves are not there only static particles upon which you placed a charge.
I.e. communication or radiation is not created by a "wave" but by something more tangiable which is a "particle" of mass carrying a charge moving at the speed of light and with rotation like a bullet so that it maintaines a straight path. The path is created by the applied current which lifts the particle like a frog experiment you dis in high school and then propelled away by the intersecting field and displacement current just like an electric train.
Cheers and Beers

A few words on hole size (perforations) and mesh material. The
particle carrying charge
is of the smallest mass possible which is why it travels at the
fastest speed known so it stands to reason that it will penetrate the
smallest hole let alone chicken wire.
Well the particle is as small as the point of a cork screw but that

same point travels in a helix around the axis point, so for penetration one has to consider the radius of the helix and its speed when looking at what hole size it can get throu as well as not adhering to the side of the perforation. Loking at a corkscrew with a large helix on it one can see that one or two will gett thru chicken wire and the rest get tangled up so yes there will be some attenuation say 3db or so but who wants a font to rear of only 3 db?
At the same time the skin depth is related to wave length but not that in air but in tne metal used for conduction So if you read somewhere chicken wire and wavelength stated in the same breath you must first think of the length of a wavelength in metal (occilation of atoms) and the thickness of the material in skin depths to determine the amount of attenuation that you want which obviously would start at somewhere in the region of 30 db front to REAR and go up from there.
See page unwin antennas or some thing like that!
Cheers

At HF, the loss mostly in heating up the conductors from IR losses. You need to get well up into UHF territory before dielectric losses start to become significant.

Indeed. 'Low-loss' coax usually has less dielectric than 'high-loss'
coax (the less dielectric, the lower the loss).

However, it isn't the lack of dielectric which minimises the loss. It is
because, for a given outer diameter, in order to maintain the same
characteristic impedance, the diameter of the inner conductor has to be
made larger - so its resistance (and power loss) is less.

Hi Tony,

Thanks...

When I first looked at your graph, for some reason I read both the
copper and the dielectric loss off the left axis, and was having a lot
of trouble believing the dielectric attenuation was that high. ;-)
There's some advantage to showing both lines with the same scaling,
since that gives a better appreciation for the relative loss in copper
versus dielectric. As your graph shows (when properly read), the
dielectric loss is a little under 4% of the total loss at 210MHz.
From the formulas above the graph (and assuming no other loss
mechanisms crept in, which they will...), the dielectric loss and the
copper loss would be equal at 146GHz! (At such a high frequency--2mm
wavelength--the line would no longer work as TEM transmission line, so
the formulas are no longer valid up there.)

A few other interesting things to note about the relative
contributions of dielectric and copper losses:

-- Dielectric loss does not depend on the line impedance, nor does it
depend on the size of the line (i.e. diameter of coax).
-- Dielectric loss (in dB/unit length) goes up linearly with
frequency,
assuming a constant dielectric dissipation factor. Expect that the
dielectric dissipation factor will go up slightly with frequency

for
typical coax dielectric, at least in the GHz region and above.
-- Dielectric loss of dry air, dry nitrogen, or a vacuum is very
low...
much lower than dielectric loss of polyethylene or PTFE ("Teflon").
The result is that foamed or other dielectric construction that's
about 50% dry nitrogen (dry air) will have about half the loss of
solid dielectric. However, at frequencies where the copper loss
strongly dominates the total loss, a more important effect is that
foamed dielectric's lower effective relative dielectric constant
results in a larger coax center conductor, which lowers the copper
loss.
-- Copper loss (I^2*R loss) goes down as the impedance of the line
increases. Loss in dB/unit length is inversely proportional to
the impedance.
-- Copper skin depth is inversely proportional to the square root of
frequency, so the copper loss of coax is directly proportional to
the square root of frequency -- at least for smooth conductors.
-- The larger the surface area of the conductors, the lower the RF
resistance and the lower the copper loss.
-- The theory is all very well, but beware how conductor braiding and
stranding, and things like small variations impedance along the
length of the line affect both real and perceived line loss.

Cheers,
Tom

What a lot of people miss is that this is the real reason open wire line is less lossy than coax -- it inherently has higher characteristic impedance than coax because of its geometry. (The I^2*R loss is lower for high impedance lines because I is lower for a given power level.)

But dielectric loss can be significant with twinlead. Water is lossy and has a very high dielectric constant, so wet ladder line or TV twinlead can actually have greater loss than moderate size coax.

What is amazing is that you can use incorrect information
to describe a patent, and no one seems to notice or care.
Such as this vital tidbit of information...

Quote from United States Patent 5,625,367
"To increase the directivity of such an antenna, a parasitic
reflector element, usually tuned to a frequency slightly higher
than the driver resonant frequency, can be placed parallel to
the driver element along the boom. For further increased directivity,
one or more director elements, usually tuned to frequencies slightly
lower than the driver resonant frequency, can be placed at various
distances along the boom on the other side of the driver element
and parallel to the driver element."

Now I don't have the degree in mechanical engineering that Art has
and may have taken advantage of before he became senile and
decided to venture into antenna design, but danged if something
in this description just doesn't seem quite right to this semi-
literate
ignorant redneck. :/

I think it gives a fairly good indication of the level of attention
given
to the claims and descriptions offered during the patent process.

BTW, don't mind Jaroslav... That's just Art's latest trunk monkey
that pops out when the red button is pushed.

I'd like to make a steal hex beam antenna for 17 and 15 meters, maybe even 20 meters. My goal is to make it is invisible as possible. Is there any ideas of what type of support poles that would be the lightest? Maybe croppy fishing poles? I'm even thinking of putting this antenna up when I use and and then bring it down in between days when I do not operate.

Your suggestions are appreciated.

Thank you.

IMO, it is much easier to make a stealth vertically polarized phased
array than try to do it with horizontal elements. Two or three
flagpoles come to mind.

I am thinking of making a 2 meter J-Pole from 3/4 or 5/8 copper pipe.

Most plans that I can find on the web call for a 58 inch main leg and a 20 inch support below, making the antenna
78 inches or so in height.

I want to install it in my attic where I have 66 inches of clear space.

Can I cut the lower support leg down to 8 inches without a major impact on the performance of the antenna?

course you can, make it from 300 ohm ribbon feeder & hang it via the top, I
did that with a slim jim which may be better than a j pole, just google slim
jim for 2 m if you don' recognise it

End fed antennas are an implementation risk.

Have you considered a vertical dipole hung from the roof structure, and taking the feedline away horizontally for a couple of wavelengths, then down. You could make it a folded dipole (TV ribbon?) and use a half wave coax balun.

Owen

The support leg doesn't carry substantial RF currents, so by itself it doesn't play a big role in the antenna.

I believe that its length is intended to help keep the current-carrying portions of the antenna (the two-arm roughly-quarter-wavelength matching section, and the half-wavelength upper radiator) up clear of the support mast, so that the mast and roof structure and etc. don't de-tune the antenna. If you shorten the support section, and bring the current-carrying parts of the antenna down into closer proximity with the attic floor, you *may* see some change in resonant frequency and SWR. However, the same would be true (perhaps even more so) if the upper part of the radiating arm comes too close to the roof.

There are several things that you can try:

[1] Try it just as you propose.

[2] Try a "Z-folded J-pole", where the support arm is vertical, the half-meter matching section is bent horizontally, and the half-wavelength radiator turns back up into a vertical direction. This sort of 90-degree bend between matching section and radiator was used on classic wire "zepp" antennas, and I've seen it used with center-fed vertical dipoles.

[3] Try an "open sleeve" J-pole. These are a bit shorter than classic J-poles - a bit tricker to make, though, since the two arms in the matching section are *not* shorted together at the bottom, and one must have an insulated mounting of some sort. Arrow makes a nice dual-band open-sleeve J-pole, and (last time I looked) they had complete construction plans somewhere on their site so you could

fabricated one yourself if you wish.

In any of these variations, you may need to tune the antenna somewhat to adjust for the antenna's shape and for its proximity to the building structure. One way to do this is to cut the pipes a bit long, and trim to fit. Placing a copper end-cap over the pipe ends is a way to extend them a bit if necessary. If you drill a hole in the end cap, braze a brass nut or two onto the hole, and insert a brass bolt, you can adjust the effective length of the arm by screwing the bolt into or out of the nut-and-cap portion.

"Fat" J-poles (with larger-diameter pipe) are relatively broad-band, so you ought to be able to tune one down to an effectively-low SWR across the 2-meter band.

[4] Build a J-pole out of 450-ohm ladder line, rather than copper pipe - suspend it beneath the attic's upper support beam using 6" of nylon fishing line, and tension the bottom down vertically using more fishing line. No need for a lower support arm at all... just short the bottom two sides of the ladder line together with a couple of inches of copper wire.

J-poles can be built in very non-traditional ways, and made to work effectively, although the dimensions may be rather different than the traditional plans would indicate. I made one several years ago by taking a bicycle flag (about 5' of thin fiberglass rod with a flag on top) and fastening ordinary hookup wire to it with black electrical tape. It took me a while (and a lot of cutting-and-trying) to figure out the right lengths for the two arms, and the correct attachment point for the RG-58 coax feed near the bottom, but I eventually got it down to an SWR of around 1.2 across the repeater portion of the 2-meter band. Fastened to the back of my recumbent bicycle, it gives much better coverage than a rubber duck when I'm riding bicycle-mobile.

My 5-band (20m thru 10m) hexbeams typically weigh in at around13lbs;
this is the weight budget:

Fishing pole spreaders (6 needed): 0.89lbs
1/4" aluminium baseplate: 1.4lbs
Spreader support tubes and fixing bolts (6 needed): 0.38lbs
Baseplate-mast fixing bracket (2 needed): 0.54lbs
Fibreglass Centre Post: 1.4lbs
Wire (5 bands): 2.2lbs

Measured Total: 13.17lbs

A J pole, or ground plane for that matter, couples into the support structure and outside of the feedline, making those conductors part of the radiating system. This alters the radiation pattern and can result in further coupling to anything near the support structure or feedline. The amount of coupling can be anything from insignificantly small to very large -- with the support and/or feedline radiating more than the "antenna" --, depending on the length and orientation of the entire conductive path to Earth ground.

We will see if the OP, like so many who implement J poles in the roof space, becomes aware of problems and comes back for advice on how to solve them.

The commonest problem is that VSWR doesn't meet expectations, but that it is the most mentioned problem speaks more of the visibility of VSWR that that it is the greatest problem with the J Pole.

Like many if not most end fed antennas, the J Pole does little to deal with the common mode current that must flow on the feed system / support structure. Explanations of how they work usually deny the issue.

But for all their faults, they spray RF around, and people would foolish to deny that they 'work' to some extent.

When you look at the strengths and weaknesses of a J Pole, they are not a good choice IMHO for in-roof-space deployment.

Owen

The 'support leg' as it is being discussed in not just a physical support for the half wave.

If the upper half wave section carries current, there must be a non zero current at the lower end of it. That current MUST exist as a common mode current on the upper part of the 'support leg' as the OP terms it and you concur.

That common mode current is a standing wave, and the distribution of it on the 'support leg', feedline, and any conducting supporting structure makes all of these elements part of the radiating system to some extent, depending on the actual geometry and their coupling to other conductors in close proximity.

So to represent that U shaped section as merely supporting structure is to deny how the thing really works... but then that is the stuff of J Poles.

Owen

Are you sure, Owen? I read it as the bottom part of the j-pole. I made a j-pole once, the top was copper, and the support was thick walled PVC. Obviously that wasn't an active part. The "u" shaped portion was all above the support leg.

The antenna matched up well with moving the clips back and forth. Still works okay. I don't look at them as any better or worse thatn a 1/4 wave gp, or vertical dipole, both of which I had before. Did not measure for feedline radiation, but I have people at home who let me know of such problems.

A discone antenna works very well with this receiver, particularly the ones with a whip above the cone. It will give adequate performance from medium wave frequencies through to UHF. You may get some breakthrough on some VHF frequencies if you live near to a powerful pager transmitter. A directional antenna and rotator can be used to overcome this sort of interference but with much greater cost and complexity.

Try the discone and see how you get on. Get the discone up as high as possible on a mast attached to a chimney above the house perhaps, or on an aluminium pole out in the garden. Try to route the cable by as direct a route as possible to the receiver. Make sure the cables and connectors are of good quality and that all joints outside are completely covered with self amalgamating rubber tape with a layer of insulating tape over the top. Use loctite or similar thread locking compound on the discone elements to stop them coming unscrewed due to wind vibration. This setup should last you several years without giving any problems.

Mike,

Even if you put a J Pole on an insulating support, or build it with flexible wire inside a rigid PVC tube, you can't pretend the the common mode current path on the outside of the coax feedline does not exist.

If you take extreme care with symmetry of the J Pole, then common mode current is lower, and with some further decoupling might be very acceptable. I doubt that common constructions achieve that goal, enquirers here and elsewhere often complain of a sensitivity of VSWR of proximity of their body and other things to the feedline... a sign of feedline common mode current.

If by a vertical dipole, you mean a coaxial dipole (though I note people are now using 'coaxial dipole' to refer to the Double Bazooka), they are also notoriously bad for feedline decoupling and need further sleeves (Bazooka Balun) or radials to effectively decouple the feedline.

The J Pole (and many other end fed antennas such as the Ringo) have a matching arrangement that makes VSWR very sensitive to the antenna's local environment. One of the most common questions is "I tuned this up real good in the workshop, and when I put it in the attic, the VSWR is 3:1".

Sure, the attic is a challenging place to put an antenna, but a narrowband matching network exacerbates the problem.

Why is the attic so bad? You have to ask is the roof conductive or variabile permittivity (under any weather) (steel, shingles, concrete tiles etc), does it have sarking or other conductive insulation products (such as foil aircell blankets) under it, or on the ceiling, does the ceiling have foil backed insulation on it, what other conductors are in

the roof space (water, gas, flues, HVAC ducts, structural steel, framing braces, wiring...etc). What works for one installation might not work for another because the installer has no idea of the installation.

An experienced eye sees things that an inexperience eye doesn't.

A well executed ground plane antenna is an antenna that a person with little knowledge and experience can implement with a high level of confidence that it is reasonably efficient and effective.

I didn't really want to can the J Pole, but to say to the OP if he REALLY MUST put an antenna in the roof space, he ought consider a folded dipole with half wave coax balun and dresss the feedline away horizontally for a wavelength or two for minimal effects on pattern (though that is not well controlled in the roof space).

BTW, a question that reveals the understanding of a J Pole by its devotees is "should the braid go to one side or the other". All three answers (yes, three) are offered in similar proportion, but I have never seen anyone support them with measurement.

It seems to me that the preferred method from purely an electrical point of view is none of those three. If you establish the tapping point, drill a hole in either tube at that point, and another at the bottom of the U, then pass the coax up through the bottom hole inside the tube (bonding the shield to that point), exit through the other hole bonding the coax shield to the tube and connecting the inner conductor to the opposite side, you have built an integral balun which helps to reduce common mode current. A further ferrite balun below the tube somewhat using say #61 would give improved suppression at 144MHz.

Owen

I assumed when he said a vertical dipole, he meant exactly that. Two 19 inch wires center fed. It's cheap, versatile, and does a lot better than your average rubber ducky.

You mount it verticaly for FM, horizontaly for ssb/cw and at an angle for satellite work.

Geoff.

I suspect you probably haven't read the thread. That was my original
suggestion with the addition of a balun and some detail on feedline
routing.

That would certainly be another workable alternative for this
situation. An SO-239, a few feet of 10-gauge solid wire, and a bit of
soldering, and you end up with a ground-plane antenna with a hanging
loop at the top, two or four ground radials drooping at around a
45-degree angle, and a near-ideal match to 50-ohm coax. Cheap and
quick to make. Stick a ferrite or two on the feedline just below it,
and feedline radiation shouldn't be a problem. If I recall correctly,
this very design appeared in the "quick tips" freebie blurb I got from
the ARRL after I first got my ticket.

>It seems to me that the preferred method from purely an electrical point

>using say #61 would give improved suppression at 144MHz.

I used that very design to build a two-arm "Copper Cactus", with
separate stubs and feedlines for 2 meters and 440. It seemed to work
well (although I never actuually measured the feedline currents).

One gotcha to this approach - you have to be *very* careful to
waterproof the point where the coax exits from the upper hole and has
its shield bonded to the pipe! If you don't get a thoroughly
waterproof coating of silicone sealant (or something similar) here,
the exposed braid will wick up water during every rainstorm which
comes along, and your coax will turn into a hose.

The SWR on mine went sky-high after a winter up in the California
rains. When I disconnected the N connectors down at the base of the
antenna, I found them full of water and algae(!) and had a devil of a
time getting things dried out again.

That is my choice for a vertical antenna hung from rafters.
I've got one in my attic. Quarter wave ground plane with
8 radials. Hung from the rafters with fishing line. I'm lucky
that my roof is fairly non conductive. All the ducts etc are
well below the antenna. I've never really like J poles for all
the reasons already mentioned. The radiator is 19 inches,
and ditto for the radials, except being as they slope at about
a 45 degree angle, they require less height than if the lower
half of the antenna went straight down from the feed point.

BTW, if you model them, the usual difference between a
1/4 wave GP and a 1/2 wave vertical usually amounts to
about .3 db... Not enough to worry about, and not enough
to make using the taller antenna really worth the extra trouble.
Not to mention the GP is much easier to decouple from the
line. And decoupling from the line is much more critical than
any extra gain from a longer radiator when used for VHF/UHF
and the very low angles most local contacts will use.
In many cases, the GP will outperform the J pole due to it's
better decoupled feed line.

814. Cushcraft MA5B Noise floor?

Newsgroup: rec.radio.amateur.antenna
Date: 2010-03-18 08:38:56 UTC
From: David <barett@blueyonder.co.uk>
Message-ID: <oElon.14389$jo6.7518@newsfe14.ams2>
Source record: 10614

If you own or have used the Cushcraft MA5B in the past could you let me know what the noise floor reading is/was and the rough height of your antenna?

I know that the noise floor will be different location to location but it will give me some idea of what I should be looking at.

I have had mine up for a couple of years now and although the signals increase 3-5 S points better than my Cobwebb and Dipole on receive the noise floor has always been S7-8 on 14MHz. It is 0-1 S point on my other two antennas. So any signal received on the MA5B less than S9+10db has a lot of noise in there audio.
SWR is good on all 5 bands.

If the noise is received equally from all directions, then the amount of noise power received is proportional to the average gain of the antenna system, which is essentially, the inverse of the efficiency of the system.

Some noise sources are not very directional, eg galactic noise. Manmade noise could me non-directional, it just depends on the physical distribution of those noise sources at a particular instant of time at your location.

You can of course determine if noise is non-directional, rotate the antenna and observe the noise level. If you want to measure ambient noise, have a look at http://www.vk1od.net/calc/anc.htm .

I calculated the expected ambient noise due to the sources discussed in ITU P.372-8 and documented it at http://www.vk1od.net/measurement/noise/FSAmbientNoise.htm , you may find it interesting. Broady, if you have a receive noise level way below that expectation, it may be sign of an inefficient antenna system.

Yes, I'll note that my installation was not particularly sensitive to
proximity.

No, this is just a dipole hung vertically, mainly because it will be
used for repeater work.

Agreed, for me at least, putting an antenna in an attic is a last
resort. I came into this thread sideways, hence some of the confusion,
but if I needed stealth, I'd probably make a ground plane out of pipe
that fit nicely over one of the vent stacks above the bathrooms.
Inside, I would go for a dipole of some sort, not a J-pole.

we're pretty much on the same page here, any issues are there because of
the point at which I jumped into the conversation.

I may ask some questions about the stack antenna in a new thread.

Hey all,

There was a type of antenna that I remember from when I was a young'un, but I cannot remember the type that it was.

It was a directional antenna, and had three vertical sections, I'm assuming they were dipoles, but am not even sure of that. These verticals were arranged in a Y pattern, and were apparently electronically or electrically switched to modify the directivity. The ones I knew about were all cut for 27 MHz, but the specific frequency isn't important at this point.

Anyone have an idea what this type of antenna was called?. A big bonus would be if anyone knew about the design of such a beast or a reference to the design.

The noise level does not change when I turn the beam 360 deg.

I have used the Cobwebb and the Cushcraft R5 in the same location and I do
not get the same noise. The noise is also present in the audio on stronger

signals.
Its the same noise you get on a weak station, where its combined in with the audio except I get the same noise mixed with the stronger stations audio. I do not get this on any other antenna's apart from the Cushcraft MA5B.

Does any one have any ideas to what could be the cause of this?

the problem is that even a fairly low horizontally polarized antenna
will do better than a vertically polarized antenna because of the ground
reflection helping the H-pol.

At a simple level, you start with the array pattern multiplied by the
element pattern, and if the element pattern starts out a couple dB down,
it's hard to make up the difference.

Hi Richard

I read on the internet, if I use 5x FT-140-43 rings stacked and then loop the coax through 6 times it would make a good 1:1 choke balun. What do you think about this type of choke balun for the job?

Hi David,

Sounds great if you are doing it.

Are you?

If you are not doing this, or some close approximation, then local
noise is backfilling your received signals (and you are degrading your
antenna's directivity by the same lack of isolation).

If you are doing this, then you may be suffering from a ground loop.
Of course, you can suffer from this by simply trying to fix a ground
loop (there is a lot of myth out there). More could be said, but I
will await to see what you have in place.

You did give S meter readings, but with respect, they are meaningless in the context you have given. Radios are not iniversally well calibrated, and most hams could not tell us what radio setting (eg PREAMP ON/OFF) put the radio in the calibrated mode.

Remember that a directive antenna does not reduce noise that is non-directional, for all that it reduces noise picked up off the main lobe, it increases noise picked up on the main lobe.

Ok, we hear that the noise is not strongly directional. You didn't care to share how you worked that out. If you had an extremely high noise level, it would quite likely be local, that is the way of things. It it appears to not be directional, it is probably very close (ie under the antenna). It could be in your own home, it could be some kind of fault with the installation.

If it is within your own home, resolution is somewhat simplified. To clear away your own home as a source, turn EVERYTHING off and run a receiver on battery. No prizes for missing something, turn things off at the main switchboard.

Does the noise vary by hour, day? Is it the same level when all the TVs and Inverter Air Conditioners should be off.

If the noise is excessive, and it is real local, you have the choice of dealing with the source, and/or reducing your pickup (eg minimising the effects of feedline common mode current... good coax, effective connectors, an effecive balun, system grounding).

Also sounds like the old CB Moonraker.
Still have one in the basement.
It was electrically switched.
Also still have the controller.
Still want to cut if for 10 meters.
Now that the sun spots are on the way back may have to put it on the front
burner.

The receiver is an undercounter mounting Sony AM/FM, radio with CD.
Nothing great, but Sony ususally does a fair job.
Mike

I have an FM radio inside an aluminum boat. The radio worked ok with the
AC cord as the antenna but I got interference when I used my laptop.
I found the circuit that ran from the power transformer to the antenna input
on the
FM IC. I installed a connector that is used on car radios and wired the
center pin
to the foil that went to the FM IC (capacitor on pcb isolated) and the
shield side to
dc ground near the IC. I then plugged in a telescoping car antenna and it
worked
great on the bench .
So I installed the antenna on the outside of the boat and the radio inside,
now one station I listen to is weak, but if I unplug the antenna and let the
center pin touch ground of the connector on the radio it comes in great.
Just curious why it is working this way.
BTW, the mod did cure the computer hash.
Mike

I don't see what it would prove. It's a known fact that people
have made contacts using dummy loads for years.
I myself once had a qso using a light bulb as my antenna.
I didn't apply for a patent. I knew it was prior art. :/

Sounds as if the antenna is fed with co-ax and has too much capacitance
across the input. Put a trimmer capacitor in series with the centre
pin and see if that improves things. Try 2-20 or 5-50pf.

Hi Mike,

You moved the antenna.

Most loss of signal as you describe comes from not being a weak
signal, but the mixture of signals that combine negatively at some
spot due to multiple reflections. When you replaced the line cord as
antenna for this better implementation, you also found that "sour (not
sweet) spot." This can occur for any frequency with the equal
likelihood of reflections combining negatively. Move your antenna a
quarter wave and see what happens.

Your description of your having an aluminum boat almost guarantees a
multitude of RF-bright reflections. At short wavelengths, this also
guarantees many, many regions that will exhibit destructive (as well
as constructive) combinations of those reflections.

Put your antenna as far away from the superstructure or hull as
possible. This will reduce the reflection path differences.

> BTW, the mod did cure the computer hash.
> Mike

FM has what is called a "full quieting" effect. It would suggest that
your first signal levels were just barely above the level of full
quiet (and perhaps not even that good).

Richard, after I read your letter I did a little better checking and found
my signal is not weak it is to strong, I'm getting interference from other
frequencies.

Also I get stations on the wrong frequency.
I went out and collapsed the antenna to minimum about 1/3 of what it was and
my problem station is perfect and the other station I listen to is still good. The local
NPR station isn't good though. But I can download the podcast of Science Friday :-)
Thanks, Mike

Hi Mike,

Normally, a too strong signal is not a problem with FM as FM literally locks onto the strongest signal and rejects the competitors. This is not a characteristic of the RF wave, but rather the modulation employed.

Collapsing your antenna is the same thing as moving it.

Now, as to your experience of receiving signals on the wrong frequency, that is a classic situation of image rejection being poor due to the lack of a tuned front-end (something that dissappeared with the dinosaurs). If I were to guess on the basis of 40 year old experience fixing these suckers, your off-frequency signals are probably shifted by twice the IF frequency of your receiver. The classical FM IF frequency of 10.7 MHz might apply, but time has marched on and designers may select their own. This old standard would argue that you shouldn't experience images except where they would be out-of-band (the 88-107 band with this IF would force that). A simple test is to tune into at least two of these off-frequency stations, note what frequency they should be and subtract the frequency where they appear. If you are having image issues (no, this is not a self-help hint), the two or more stations should come up with the same differences.

If you come up with the same number, AND you have trouble with interference from adjacent stations (there are guard bands to prevent this), THEN you have one crappy receiver.

The usual, lousy FM tuner. They don't make'em like they used to. It's
the same with television sets, one large signal and they fall off the
rocker.

If you have a radio with a signal strength meter you could notch out a
strong station. But that only works it it's just one and far away from
the NPR frequency. The only other options are to get a better radio, a
directional antenna, or just live with it and use the podcast.

One solution: Try to get an old Becker car radio. And I mean old, at
least 40 year, the first transistorized ones that could still be
switched to 6V. They used to be standard issue in Mercedes Benzes.

Well the boat is a pontoon boat (maybe $6,000) that I run my business
from, my wife or I are on the boat 70 hrs a week.
The radio was fine when I used the original AC cord antenna, except when I
was on my laptop, it caused hash
in the audio. That's why I isolated the antenna from the AC, that did
eliminate the computer hash.
I have put together a car radio and wall wart that I use with a pillow
speaker at night. Maybe later I'll put
together another one for the boat.
Mike

I did not offer to have a QSO for cash. Obviously you cannot read.

You accuse me of being dishonorable and then call me an idiot. Quite
the gentleman.

You also say I offered 1000 dollars for something a year ago. You are
hallucinating again.

And then you give a backhanded insult to me, and to women.

You should be quite proud of yourself.

So, as I offered several days ago, and you didn't respond to, how about
a QSO on your wonder antenna?

I will require an impartial observer to give evidence that you actually
use the "Faraday Shield Thingy Antenna" you think is so wonderful, since
I also believe you not to be a man of honor.

Jaro.

Please reread all of what was in the posted sequence you are
referencing. Exactly what I wrote is near the top end of what is in
this very message.

I never offered anything to Art, I wagered that others would not be able
to have a QSO with him. Implying that they wouldn't be able to hear him
if that helps you understand.

You would be surprised as to what a heart attack can do to you.I have seen people reduced to just a shell of their former self. My heart attack required open heart with five bypasses, then the addition of a pace maker then a removal of same when the line to my heart went septic.A bit later my gall bladder was to thin to take out via micro surgery! I think if you look around a bit more you will find people a lot worse off than me that would keep you in the business of making a laughing stock of for a long time,..... until it happens to you. When things like that happen it behooves one to try and overcome the drawbacks so that life is still worth while living. Ofcourse there are always people that are rude and sneer but you learn to get over that and keep on slogging. At the moment I am really enjoying my life and hobby and believe I am doing pretty good regardless of the rude jabbing that I am getting. So you do your thing while I continue with mine.

** Hearing the same FM station at more than one spot is still possible even with a 10.7 MHz IF frequency - if the signal is very strong. The reason is harmonics of the incoming carrier generated in the RF stage interacting with harmonics of the local oscillator in the mixer.

Eg:

A 100MHz FM carrier generates a harmonic at 200MHz in the receiver.

When the local oscillator is adjusted to 94.65 MHz, its second harmonic is 189.3 MHz.

The difference frequency is then 10.7 MHz - so goes through to the FM detector.

In this situation, the FM deviation is doubled so the recovered audio will be distorted on loud passages.

.... Phil

in a very crappy receiver. It has already been said.

Not the usual quality one expects from Sony, but Mike's testimony
suggests otherwise hence we cannot discount a comb generator having
been dropped into the LO chip's place. Pity that, it must have been a
bad year.

It sound like the "Luxemburg Effect". The signal was from the dipole
antenna.
Are now the FM stations which use the dipoles?

The usual solution on boats: Use a decent car radio.. Well shielded, expects outdoor antenna. Runs on 12Volts... Can be had with CD player, separate input for your Ipod etc.., good audio power to speakers etc.... And designed to work inside a metal vehicle....

This morning I got on the boat and the signal that was improved to good by
shortening the antenna is now bad. 94.5 has interference from 101.1.
Oh well!
Mike

You really need a better quality radio and with radios and a lot of
other stuff older = better :-)

I mean, considering what the boat must have cost ...

I have learned not to trust any radio that's newer than 30 years,
whether name-brand or not. And that's from experience. Unless it is from
companies like Icom.

Best of all, it can be bolted down. That's really important on a boat.
However, many newer car radios (newer as in "last 20-30 years") don't
have very good tuners. Best to get one from the era of Ge-transistors,
those radios were usually good.

Better yet, get an Icom, Yeasu or whatever comms receiver. Most have a
WFM setting. Ok, no stereo sound but one can easily listen to NOAA
radio, ship-to-shore channels and so on.

Or a tuned trap to reduce the signal from that one station.

864. Radiation penetration/absorbtion

Newsgroup: rec.radio.amateur.antenna
Date: 2010-03-21 04:49:42 UTC
From: Art Unwin <arthurunwin@gmail.com>
Message-ID: <d8484c08-9c23-478b-b58b-acc49ddccc83@e1g2000yqh.googlegroups.com>
Source record: 10664

If on places a am/fm radio inside a box made of thin aluminum foil the
radio will be able to hear am broadcast band but not the fm band.
(Experiment by Harvard in Boston)
Intuition tells me that when using a perforated plate the lower the
frequency then the smaller the perforations in the shield to create a
blocking effect. This would, I believe, opposes the progression of
skin depth with respect to frequency.
The books state for a mesh shield the perforations should be less
than 1/10 of a WL which on the surface opposes the results obtained by
the box experiment! Is the difference involved with calculations
changes for sheets that are thinner than skin depth such as circuit
board traces or something else?
Where has my intuition gone wrong in opposing the books?

> (Experiment by Harvard in Boston)

Yes, because the attenuation from an enclosure is made up of a
reflection loss and an absorption loss. The absorption loss is
proportional to both the thickness of the material and the frequency (
amongst other things). So a thin shield will have less attenuation at
low frequencies.

> Intuition tells me that when using a perforated plate the lower the
> frequency then the smaller the perforations in the shield to create a
> blocking effect. This would, I believe, opposes the progression of
> skin depth with respect to frequency.

Why does intuition tell you that? My intuition tells me that you need
smaller holes as you increase the frequency?

Also when you refer to the size of holes are you referring to their
diameter, spacing or both?

> The books state for a mesh shield the perforations should be less
> than 1/10 of a WL which on the surface opposes the results obtained by
> the box experiment!

Why? The box had no holes! Adding holes will just degrade the screening
from the starting point of a continuous screen. The larger the
diameter of the holes the worse the screening will be degraded at a
particular frequency, and the degradation will also be proportional to
wavelength, large holes wrt wavelength, the more signal will leak through.

Jeff

If I can't see the other half it is the monopole.
So I repeat my question: Are now the FM stations which use the dipoles?

>and Luxembourg has nothing to do with it, your silly frequency
doubling notions should be packaged up in art's box and never see the
light of day.

The dipoles have the directional pattern like this:
http://www-antenna.ee.titech.ac.jp/~hira/hobby/edu/em/dipole/index.html

It looks like the interference of the many sources (dipoles have the two).

The two sources not in phase double the frequencies.
S*

so why when i switch my transmitter from a 'monopole' where YOU can't
see the other half to a dipole does the frequency stay the same?

Your transmitter has the same but in the receiver antenna is possibility
that appear the doubled frequency.
Luxembourg effect was observed in 1930. Now radio people manage with
eliminating it.

The Luxemburg effect is usually contributed to the suspected Radio
Luxemburg intermodulation products caused by the _ionosphere_
nonlinearities.

Similar intermodulation effects can be obtained by the nonlinearities
caused by rusty bolts in a transmitter tower.

nope, the receiver still hears the proper transmitted frequency.

You significant lack of understanding of dipoles is causing you to ask
silly questions that are meaningless.

This shows effects over a 48:1 frequency range. The FM band represents a
1.23:1 range. The image has no bearing on the topic at hand.

> It looks like the interference of the many sources (dipoles have the two).
>
> The two sources not in phase double the frequencies.

This is completely wrong. In a _linear_ systems adding two signals
cannot create new frequencies, including doubling. In the frequency
domain this is clear. If you look in the time domain and look at zero
crossings you may be confused. Do the math for the addition of two sine
waves of different phase. Stop relying on internet images you don't
understand and may not have any relevance to the discussion.

You can do the math in the time domain, or frequency domain. Either
should tell you there is no doubling of frequencies.

In order to generate new frequencies you need to have a non-linear
effect. Addition is NOT a non-linear operation.

What did the Harvard experiment in Boston describe as the cause for this? Some vague reference to an experiment somewhere does not show anything. Provide a proper link if you want anyone to take the reference seriously.

> Intuition tells me that when using a perforated plate the lower the
> frequency then the smaller the perforations in the shield to create a
> blocking effect.

I believe this conflicts with your particle concepts. Why should hole size have any effect on spinning particles of different frequencies?

You position also is in conflict with general understanding. If you are correct, what hole size blocks very high frequencies. You concept would result in a simple wire frame enclosure.

> This would, I believe, opposes the progression of
> skin depth with respect to frequency.
> The books state for a mesh shield the perforations should be less
> than 1/10 of a WL which on the surface opposes the results obtained by
> the box experiment!

You may be ignoring the differences in the antennas. AM may have used a ferrite loop, while FM may have been a whip. (We don't know because you provide no details.)

Could one antenna be responding the magnetic component of the signal more than the other? (We don't know because you provide no details.)

> Is the difference involved with calculations
> changes for sheets that are thinner than skin depth such as circuit
> board traces or something else?

Type of materials, type of antenna, relative dimension may all play a factor. You need to determine all of the effects that enter into the situation and not focus on one or two.

> Where has my intuition gone wrong in opposing the books?

Probably because you don't pay attention to the details and are relying upon an understanding of the topic that is not correct.

I doubt that ionization in the atmosphere has anything to do with what
is being observed.

However, overloading or cross modulation in the receiver is much more
likely.

Thanks first for your thoughtful response. The article mentions only
skin depth and frequency applied so in effect frequency is the only
variable
Agreed
The above states that as you go down in frequency (a longer
wavelength) that it becomes
easier for propagation to be available at the other side. Stated
another way the deeper the
the skin depth the more penetration occurs
>
> >   Intuition tells me that when using a perforated plate the lower the

> Why does intuition tell you that? My intuition tells me that you need
> smaller holes as you increase the frequency?

The experiment shows that it is easier for the lower frequency to
penetrate to the other side than the higher frequency. Or another way
as you move higher in frequency a better blocking effect occurs. If I
add perforations the same progression arises with respect to hole
diameter. (Note in the experiment we only have two variables, skin
depth and frequency, everything else is seen as a constant by the
experimenter. Not knowing the thickness of the screen could possibly
bring us into the situation of circuit boards where the skin depth is
deeper than the trace thickness but that may be a red herring)
From my perspective adding holes will provide the FM wavelengths more
leverage
to penetrate to the other side!

>
> Also when you refer to the size of holes are you referring to their

agreed

> Jeff

I used the perforations as a method of reducing the screening in both
cases to make a point

Jeff, I am stating that my path of thought took me into a different
direction from the books.
Thus I have to assume that my logic or aproach is in error. The
question thus is where is my error , That is where I need direction?

Well, that's what I suggested above, notch = trap :-)

But it's tough and can be impossible if there are useful weaker stations
near the one you want to muffle. In Europe they had a pager service
right at the lower end of the FM band. Whichever committee signed off on
that one should be dunked into a moat for gross incompetence, until they
either learn or quit their career. Anyhow, the inevitable happened, and
despite being a school kid I predicted that: A barrage of complaints by
FM listeners. In Germany they pay a radio tax so that makes them sort of
constituents with rights. Long story short the governement had to
furnish rather expensive notch filters to anyone who complained.

Thanks for your response.
The article only gave me the given facts for the experiment and
nothing more.Yes my concepts on radiation are in opposition to the
norm so I am using the facts presented as a way of destructing or
confirming my perceptions.
When I read up on Faraday shields the concept of "particles"
predominates as opposed to "waves" without exception and I am trying
to make some sense of these differences when considering propagation.
With respect to receive of the radio. Since the foil is flat and
without perforation it should be sensitive to everything thrown at it.

Shielding and grounding is a secret science, so secret and of military
importance that Don White Consultants would not teach foreigners
(damned furriners) how to shield a building from EMP.

If I can here a weak station on any of my other antennas that is fully
readable but weak and I then switch over to the beam the station gets lost
in the noise.
On stations that are a bit stronger but under a S9 after switching to the
beam then there is a noticeable amount of noise in with there audio. Of

course the beam brings the whole signal in a lot stronger as it should do with but with this large increase of hiss/background noise that is some how mixed in with there audio that wasn't there before.

I do not get the same noise on any of my other antennas even when they are positioned in the same spot as the beam and connected to the same coax line. I have tried the Cushcraft R4 and the R5 the Cobwebb and several mobile whips and I do not pick the same noise up..

I have had the MA5B down and I cannot see any thing wrong with the installation.

I have ordered some Ferrite and I will make a coke balun up and see if it improves.

I will let you know what happens.

If it is this article,
http://www.fas.harvard.edu/~scidemos/ElectricityMagnetism/SkinDepth/SkinDepth.html
Then more was given.

It was an experiment in skin depth.
AM was significantly attenuated, too.
It specified the frequencies used and the associated skin depth.
The radio is also specified.

Using an extremely cheap radio as a measurement tool is not sound
technically.

> Yes my concepts on radiation are in opposition to the

Perhaps it is a problem with how you do searches. On this page
http://en.wikipedia.org/wiki/Faraday_cage
There is no mention of particles as the means of transport to the
shield. Electrons are mentioned as they are part of the cage and respond
to applied fields.

> With respect to receive of the radio. Since the foil is flat and
> without perforation it should be sensitive to everything thrown at it.

But the experiment in question is about skin depth which does vary with
frequency.

Unless, of course, you are talking about some other Harvard article, but
we only have to guess, because you still don't identify it.

How do you expect us to know what you are really talking about?

In reality no sine waves. In the ends of a dipole the voltage is doubled
(VSWR) and the strong picks are radiated.

>Stop relying on internet images you don't understand and may not have any

Discussion is on the harmonics. The dipoles can produce the frequency
doubling.
>

In the school math the water waves are transversal. Look as they are
like: http://en.wikipedia.org/wiki/Stokes_drift

> In order to generate new frequencies you need to have a non-linear effect.
> Addition is NOT a non-linear operation.

The two picks from the ends of the dipole are not linear.

Are such products the hours independent? Is ionosphere all time the same.
The dipole on the tip top of the mountain (the both end of the dipole were
:seen") produced the doubled frequency.
>

The same was obtained in Warsaw tower (collapsed years ago).
Now Warsaw use monopole.

So you move the trap slightly to one side. A good trap can be narrow enough to only affect one or two channels if it is built with the right components, but it isn't cheap. Glass piston capacitors and glass inductors are temperature stable and have a very high 'Q'.

The aether waves were, are and will be a secret. But we all want to guess
like the things are.
Fortunatly the papers by Stokes, Kelvin and many others are available on
line.
Maxwell, Lorentz and Einstein are for teaching.

> to applied fields.
Yes they clearly state electrons which is a particle. It is extremely
small and of minimul mass which is why Einstein states that the speed
of light is a maximum.
The article you point to shows charges or fields which must be carried
by something like particles as proven in other theories such as
Quantum theory.
Fields and waves book by Ramo etc constantly lean on boundary laws
thru out there book and boundary laws clearly state the relationship
of static particles to equations relative to radiation.
If we are to refer to waves then accelleration demands mass so we need
a connection between waves and mass.
Assuming it is a wave that impinges on a Faraday cage we then have to
determine what half a charge comes about so that the charge cancels
and thus reverts to a time varying current. Again another puzzle!
Anyway the article that you point to shows a point charge which is
certainly not a wave which would be represented by a line of the
length used in top band.
As far as penetration goes the mass involved is always of the same

mass and ikt is only the charge that varies in frequency as shown by
the radius of spin in helical form of the charge.Thus again we have to
find a connection between wavelength and charge.Another obstical....
If you can point out why one cannot use boundary rules so that
particles are recognised as the carriers of charge the same as with
Quantum theory I would be very gratified. None of the group excepting
newcomers such as your self has provided proof of the inelligability
of my approach so I am forced to explore other facets
of radiation to determine why my aproach is in error.
I apologise for not being clear in the subject that creats problems
for newcomers such as yourself but to re iterate the discussion which
has been going on for years would be quite a hardship. However if as
a newcomer you can supply why static particles cannot be associated
with propergation you would be doing something different to the group
that are relying on zero facts and replacing it with insult and spam.
Thanks for responding in a sensible way .I would like to point out in
addition that existing antenna programs with optimizer based on
Maxwells equations rely very heavily on the maintenance of equilibrium
which is the foundation of my aproach which includes particles and
certainly not waves.
If we are going to throw out such programs we surely must know why
before we take such a step when the presence of particles appear to be
in the majority of aproaches.
Best regards
Art Unwin.......KB9MZ.....xg

> How do you expect us to know what you are really talking about?
I am fully aware that I am not clear with my questions but I have to
live with that.
The point is that I am still trying to find out why the group does not
accept the extension of a static field in equilibrium cannot be
connected to Maxwells equations when adding a time varying field a
train of thought covered by boundary rules that are used in many
places.
If we accept the above then we have agreement with

Sorry Owen. I forgot to put this in.
I have turned all power off to the house and ran it from a battery. There wasn't a lot of difference.

Maybe its coming from a neighbours house close by or the overhead power lines on poles that feed all the homes along this road. I noticed today there are also some that feed power to the homes over the back as well. But that doesn't explain the fact that I do not get the same noise from any other antenna. All antenna tests were all done in the last couple of days.

If the choke doesn't work then I will bring the antenna back down and take it apart and start a fresh rebuild.
The only thing I can think of that is different is that I used some special grease from Vine Antennas on all the joints that was advertised for antenna joints.

David

Strictly speaking the page describes a demonstration from page 321 of
this book:

G. Bekefi and A. H. Barrett, Electromagnetic Vibrations, Waves and
Radiation, (MIT Press, 1977)

http://www.amazon.com/Electromagnetic-Vibrations-Radiation-George-Bekefi/dp/0262520478

http://mitpress.mit.edu/catalog/item/default.asp?tid=7576&ttype=2

A reviewer comments, "MITonline offers the course based on this book
for free. The course is great! This book is a less engaging, but a
more comprehensive version of A.P. French's original text for the
course. There are many gems in the book, such as insights into
microwave oven fundamentals, that are not present in basic texts.
Beware the softcover binding, it needs a gentle hand. "

892. Noise Prediction

Newsgroup: rec.radio.amateur.antenna
Date: 2010-03-21 20:49:03 UTC
From: Oliver Mattos <omattos@gmail.com>
Message-ID: <a7302e8c-254d-47d4-87cb-1947522d6938@x12g2000yqx.googlegroups.com>
Source record: 10692

Hi,

All the communication equations and formulae today I know of (eg. the Shannon-Hartley Theorem), give limits on data transmission given certain signal and noise power levels.

Most models assume that the data received is the sum of the original signal and Gaussian noise. More advanced models assume a transfer function is applied to the signal to simulate multipath, and other radio phenomena.

My question is that since in many cases at least part of the noise is not entirely unpredictable, it seems like if it could be predicted, then it could be subtracted from the received signal, therefore not counting as noise as far as the Shannon-Hartley Theorem goes, therefore allowing a higher channel throughput when all other conditions are the same.

Examples of "predictable" interference would be EMI from other man-made devices, such as oscillators in power supplies.

My idea for doing this would be to receive a given signal (assumed digital), demodulate it and apply error correction to obtain the original data. Next, re-encode and modulate the data just like the transmitter did. At this point, the receiver has a precise copy of the data transmitted. Next apply a transfer function which simulates the channel (this part would have to be self-tuning to minimise error). Now the receiver has a copy of the data as it would have been
received if there were no external noise sources (but including the effects of signal reflection and fading, which would be included in the transfer function).

Next, the receiver could subtract the "ideal" received data from the actual received data, obtaining the noise received. Of this noise, some is predictable, and some is truly random (assume true Gaussian). This data could then be Fourier transformed, time-shifted, and inverse
Fourier transformed to obtain a prediction of noise, which could then be subtracted from the incoming signal for the next piece of received data.

Similar ideas could be used for removing unwanted signals. For example, imagine two people are transmitting on the same channel. If you know what type of modulation and error correction they are both using, it seems feasible that one signal could be decoded, subtracted

from the incoming signal, leaving enough information about a weaker signal to decode that as well. If neither signal can be decoded "first" (ie. when treating the other signal as random noise), then I guess using linear equations to represent the data streams, it is still possible to decode them as long as the sum of signal data bandwidths is less than the channel capacity.

Would any of the above sound vaguely plausible? Has it been done before? How much of real-world noise is "predictable"? How complex would my noise prediction models need to be to get any real benefit? Is this the kind of thing I could investigate with a software defined radio and lots of MATLAB?

Thanks
Oliver Mattos

What does the book point to, waves or particles? We all have plenty of
books and all cannot agree on the subject on radiation! In other words
they have placed their own interpretations of the observations seen
with the double slit experiment as over ruling of all and cast in
stone. This is what the physics forum sponsered by Scientific American
said to me as they banned me because of my temerety in challenging
their position.In addition they stated that it is not possible outside
the physcics spectrum to challenge anything which thus puts all in the
spectrum of crackpots. Dr Davis of MIT provided the mathematics
that confirmed the presense of particles, but mathematics was not
considered a reputable answer compared to the majority argument that
the mathematical aproach was illegal.
So waves hold the majority in the books but by its very presence all
understanding of radiation has been stymied for the last hundred

years by the resistance to change without any accumpanying facts and where physicists refuse to review to re examine what they state is now "cast in stone." New books are written every year via plagarisation for personal profit where the professor orders purchase of such books for his pay off. Not one has come out with a review of radiation and why progress has been stymied. And that goes for Radcom and QST who have no real interest in advancing the hobby of its members.

These compounds are often a waterproof grease of some kind with granular
metal particles, often zinc. The concept is that the grease excludes
oxygen and water from the joint and so reduces corrosion, and the
irregular zinc particles improve conductivity by 'punching through' the
oxide layer on the aluminium.

It is conceivable that the stuff you have used may create some kind of
galvanic action which could produce some noise. The goop that I have used
has always worked without apparent problems, but it will depend on the
recipe, and different recipes exist for compatibility with different
metals.

BTW, it is my experience that marine grease does just as good a job on
clean aluminium without being nearly as messy. I use a small stainless
wire brush in a dremel tool to clean the inside of mating tubes, a
regular stainless scratch brush to do the outside, and a little marine

grease on the mating surfaces. Don't be overzealous with the wire brushing as you embed steel in the aluminium. People often propose non-metallic scourers, but they also embend non conductive material in the aluminium surface.

Have you looked for other current loops that could generate noise, AC and DC. DC loops can be 'powered' by galvanic action from things such as mixed earth electrodes (eg copper or copper clad electrodes bonded to galvanised iron water pipes or masts).

Owen

Try thinking in terms of fields and charges.

A puzzle because you apply your misconceptions BEFORE first
understanding what is there.

> Anyway the article that you point to shows a point charge which is
> certainly not a wave which would be represented by a line of the
> length used in top band.

Only because you interpret it that way. The article does not mention
point charge as causing the behavior, externally applied fields are
mentioned.

> As far as penetration goes the mass involved is always of the same

Gauss' laws refer to flux and do not require carriers of charge to exist.

None of the group excepting

A lot of that has to do with your inability to communicate adequately.

If you are trying to present a new concept, then it is up to you to show
why, and that, it is right. Do that in a clear convincing way, with the
appropriate math, and you might foster a worthwhile discussion.

The wrong way to do this is throw a half-baked idea out and expect
others to accept it. You'll never prove a point that way.

Which of these antenna programs have you analyzed to the level to make
this statement? Have you looked at the source code of the programs?

> If we are going to throw out such programs we surely must know why
> before we take such a step when the presence of particles appear to be
> in the majority of aproaches.

Why throw out the programs? Using waves is perfectly correct and
adequate for them.

Waves provide an adequate model for propagation. Particles may be
adequate at the quantum level. Both are ways to describe something.
Neither may adequately describe thing in all cases. They are models for
what happens. As long as the models are applied appropriately, there is
no problem. Applying a model inappropriately is bound to cause problems.

That is solely because YOU can't describe your concepts adequately.
Putting "+t" on both sides of an equation does not necessarily lead to
anything meaningful. IF you were to describe your thoughts adequately,
perhaps someone would show you where you make errors.

Ok so you are not interested in a debate. I thought that as a newby
you might just be a little uncomfortable with the idea of using
Quantum theory if you desire particles or to use classical physics if
you desire waves. Obviously it is very difficult to accept change.
Any way thanks for your response and the technical data you supplied
for all to digest.
Regards
Art

Art,
You seem to be the one avoiding a discussion. When the conversation does
not go your way, you call it quits.

I do my part in responding to your points and pose some questions of my own.

900. Re: Noise Prediction

Newsgroup: rec.radio.amateur.antenna

From: Mike Kaliski <michael.kaliski@tesco.net>
Message-ID: <7_mdnSNEX-EYJTvWnZ2dnUVZ8nGdnZ2d@bt.com>
Source record: 10501

Hi Oliver,

There are essentially two types of noise or interference to signals. Random or white noise is the product of the cosmic microwave background picked up by an antenna, atmospheric interference and also thermal effects on circuit components. This noise cannot be predicted by any currently known method because it is truely random.

Interference from man made or some natural sources can be regular and it is possible to partially or almost totally negate the effects in some cases.

The signal to noise ratio of a signal can be improved by increasing the power of a transmission, reducing the bandwidth of a transmission (effectively increasing the power because the signal is confined in a narrower bandwidth), slowing the data rate of the transmission, repeating certain elements of the transmission or implementing error correcting routines to correct for errors in a received signal. Any or all of the above methods can be combined to give a robust receiving system with the proviso that the signals to be received are not completely swamped by random noise.

Good examples of these methods in use can be seen in reception methods used around 136kHz where very narrow bandwidths, slow transmission speeds and strong error correction allows reception of signals that are not audible to the human ear. That said, the human brain does have a remarkable capacity to pick signals from random noise due to our inate ability to try and pick patterns out of everything we see or hear. A skilled operator can decode a single weak morse code signal in the presence of heavy atmospheric noise and interfering signals from several other stations near the same frequency.

I think a lot of what you are asking about has already been done to a pretty high level and you may well be able to build upon the current methods and come up with some improvements. What you will not be able to do is reconstruct a signal that is not there because it has been totally drowned out in random cosmic, atmospheric or thermal noise.

There is no antidote to true randomness. It's like adding infinity to infinity, you just get infinity (and that could be more or less than you started with depending on the maths you are using).

Have a look at some of the freeware SDR decoders that are around for digital receivers and perhaps purchase one of the cheap Softrock receivers that Waters and Stanton sell for around ï¿½20 to carry out some experiments. With the right software and a decent audio card, these receivers can rival the performance of the top end commercial offerings although only on a single band. With some real world experience, you will soon find out what you are up against. Not an easy project, but a very rewarding field of study.

Art,
You seem to be the one avoiding a discussion. When the conversation does
not go your way, you call it quits.

I do my part in responding to your points and pose some questions of my own.

Joe, I wanted a debate as to why adding a time varying field to a
boundary enclosed static particles in equilibrium is illegal. This is
in opposition to what the books say.
My whole theory lives or dies on how this is resolved. Nobody will
provide technical details as to why this is illegal. I supplied what I
believe supports the idea but nothing can be considered "proof" to
those who oppose change. If computer programs support retaining
equilibrium at all times then that is an independent result. If
Quantum physics chooses
particles over waves again that is an independent result which
questions conventional judgement. To accelerate a charge in the form
of a wave is un explainable in present science.Nor is the division of
same explainable with respect to the Faraday cage,
To provide an accelleration mass is a must but how a wave provides
such is stated no where. All of these in my mind questions the
validity of using boundary laws for which one
must also reflect equilibrium i.e. is it illegal? Why is it illegal?
It does follow the laws of Newton therefore Newtons laws are at
risk.Yes we are talking about the movement of flux
but movement requires the addition of time. So again the salient point
in this debate is the
addition of a time varying field to an arbitrary boundary containing
static particles deviate from the requirement of equilibrium in all
laws. Namely all statistics are placed on one side
of an equation that equals zero is a specific requirement. "Equal"
really means "equal" and not close enough for horse shoes.
For any sort of debate this central question must be resolved at the

beginning or there is no debate. Resolving this allows for progress into other areas all of which depends on the above question. If nobody can demonstrate why it is illegal then proof or truth is not attainable. If we cannot debate technicalities of radiation then the group is left to exchanging insults and spam or poll counting

It's probably a severe impedance mismatch between your new antenna and
the old pickup coil. You might need to create a little step-up
transformer between the board and jack. I looked at a few FM chip specs
and they leave it up to the designer to figure out the right input
transformer. You'll probably need trial and error to figure it out.

What does the book point to, waves or particles? We all have plenty of
books and all cannot agree on the subject on radiation! In other words
they have placed their own interpretations of the observations seen
with the double slit experiment as over ruling of all and cast in
stone. This is what the physics forum sponsered by Scientific American
said to me as they banned me because of my temerety in challenging
their position.In addition they stated that it is not possible outside
the physcics spectrum to challenge anything which thus puts all in the
spectrum of crackpots. Dr Davis of MIT provided the mathematics
that confirmed the presense of particles, but mathematics was not
considered a reputable answer compared to the majority argument that
the mathematical aproach was illegal.

So waves hold the majority in the books but by its very presence all understanding of radiation has been stymied for the last hundred years by the resistance to change without any accumpanying facts and where physicists refuse to review to re examine what they state is now "cast in stone." New books are written every year via plagarisation for personal profit where the professor orders purchase of such books for his pay off. Not one has come out with a review of radiation and why progress has been stymied. And that goes for Radcom and QST who have no real interest in advancing the hobby of its members.
Regards
Art

Art,

The double slit experiment clearly points to particles or photons. The slits are very narrow (otherwise the experiments don't work) and the wave like properties are caused by the interaction of the particles with the atoms in the walls of the slit as they pass through. The slit is modulating the particles if you like.

We know that individual particles are involved because they can be counted one by one through a detector.
We know that wave like properties are involved because of the effects observed on a screen placed behind a diffraction grid.

The observed properties are due to influence exerted on the particles as they pass through the diffraction grid by the atomic structure of the grid itself. Unless the experiment were carried out at absolute zero, the atoms in the walls of the slit are vibrating and must influence the photon as it passes through.

At absolute zero, nothing would be moving, including the photon, so the experiment collapses at this point.

Photons are particles that display wave like behaviour under particular conditions.

I totally agree. Many things have attributes that other things have
but humans say that if it has a tail like a dog then it is a dog!
History shows that the interpretations ascertained from this
experiment was expanded to provide data to conclusavly say that
radiation" is" a accellerated wave and that is carved in stone i.e.
conclusive by physicists who made that descision without over sight
from another discipline.Cast in stone is a finality for physicists
who time after time dtate that their manipulation of mathematics prove

the existence of another particle that is predictable but we have just not found it!
Now the shoe is on another foot, I have to provide an alternative PLUS prove it where others don't have to.
To respond I used EXISTING LAWS and the mathematics that represent them. Gauss stated his law as a measure of "an instant" in time recognising that flux is mobile where at any "instant" of time the boundary was in equilibrium. So I added a length of time where a time varying field was added. All this being in cgs units. When the units were changed to be the same as Maxwells equations (MKS) they showed that they were one and the same which cemented the position of particles as being present in the makings of radiation.
I am using common mathematics with established accepted laws and nothing more but I am being asked to prove its legality which is beyond reason.This establishes some consistency in the use of both classical and other strains of physics that when applied to the same problem also provides the same answer. What more can be said? Articles now declare that interpretations made years ago are not as we thought, but it is to late now for change as decisions in physics are the result of polls and not reality.

As I run through some other physics books I see situations that abound
where a static field is made dynamic! It just doesn't make sense that
hams who consider themselves as experts with respect to antennas can
now suddenly declare that it is now deemed illegal
I suppose with respect to free speech one can say anything if they do
not care about their credability of being an expert.This is not just a
single ham but the majority of the hams
commenting on this group. If a poll is taken then hams have proved
them selves to be in the right and truly expert.

What fraction of the ham population is on r.r.a.a. do you think?

Odd question but I will respond to prevent bad thoughts.
For this group this discusion has lasted several years and only two
agree that the theory is worth reviewing. On qrz there have been two
threads which has in the order of 8000 + views including a posting by
Tom W8 TI which pleased me as he always follows up with a full
analysis that destroys various claimes put forward. This time he has
failed to place his resonings in writing so basically he is agreeing
with other hams that it is a fraud. Nobody on QRZ expressed any
confidence in my theory and again nobody provided anything to back up
the opinion of fraud. If one went by poll within the amateur group
there would be rousing agreement that it all is a fraud both in
thought and action. If one was judged in terms of debate then it is
two to zero as they were the only ones to express "why" it was worth
consideration. So If hams are the experts they think they are they do
not have to prove their competance and just go by the polls.
As an aside Jeffries who is the antenna adviser for a U.S.magazine
stated that static had no part in ac or dc circuits. I believe he is a
professor or teacher at a university in Sussex U.K. having held
similar positions in the U.S.
I believe that the above answers are the truth as I see it and what
you asked for.
Kotar has been the most critical and I leave it for you to review the
archives for his postings explaining his position which appears to be
par for the course on this newsgroup.

No I was banned for not conforming with known physics which was
considered arguementive. I was given the option of showing an
understanding and aproval of known physics for reinstatement. I
supplied such information to you as a sample of the truth regardless
whether it was in my favour or not knowing full well one might seize
upon it
to my detriment.

Yes. THY receiver is tuned to the transmitted frequency.
Luxembourg effect means that another receiver tuned to the doubled your
frequency hears you.

I am not able to measure the shape of the picks.
You all can.
You can also check the "addition of two" picks (solitons).

If reality will help shape your intuition, then you may be interested
in this paste-up from an IEEE paper linked below.

Note that the spacing of the conductors in the mesh forming these
cavities is much greater than your intuition says is required "to
create a blocking effect."

Perhaps you should read up on what the Luxembourg Effect actually was!!

It had nothing to do with antennas!!

It was Cross Modulation in the ionosphere between Radio Luxenbourg and
other radio stations, where by the modulation of Radio Luxenbourg was
heard superimposed onto the second station.

Interesting. thank you.It would appear that they are using approx .1
lamda sections but the beam pattern appears to be what is expected
other than the differential between E and H
as shown on my page.
Ofcourse it doesnt show how it is fed which can make a lot of
difference.The size of the squares really determine whether the
currents slides across the surface or follow a paths per a normal
radiator. I certainly would not feel comfortable using such openings
as protection against lightning.

You think that's bad? Some idiot sold two way radios to a school system, and put them on a frequency reserved for ambulance service. Every time the base tried to contact one of their ambulances, the damn school bus drivers would start yelling at them to 'Get off OUR channel". The so called frequency coordinator for the area refused to do anything about his screw up for allowing them to be licensed on that frequency.

Real comfort is produced by real (proven) knowledge, not intuition.

The purposes of the gridded cavity are (1) to isolate its radiating elements from coupling into the nearby supporting tower, (2) to minimize coupling into adjacent cavities on the same level and those installed above and below, (3) to minimize the windload of the installed antenna compared to using solid cavities, and (4) to create predictable, unit radiation patterns that can be used together to generate specific, directional radiation patterns for the array that meet given specifications in the azimuth and elevation planes.

The cavity, and all of its components operate nearly at earth ground potential in the low r-f spectrum, where induced energy from nearby lightning strikes is greatest.

Arrays of these cavity antennas have been in operation at the top of the Sears Tower in Chicago and many other "tall-tower" sites for more than 25 years now, with zero lightning damage.

Source record: 10518

I know that many people think G3LHZ is a little bit off his rocker, but out of curiosity... what he suggests on slide 15 here:
http://frrl.files.wordpress.com/2009/03/isoloop_all-sorts-of-small-antennas-better-by-heuristics.pdf -
- is that a valid approach to measuring antenna efficiency? -- Use a thermal camera to note how much an antenna heats up with a given input power, find out how much DC power it required to heat it to the same temperature (the antenna's loss), and -- poof! -- antenna efficiency = (input power-loss)/input power?

What are the significant loss mechanisms that he's not accounting for? (He claims his matching network isn't getting at all hot.)

Thanks,
---Joel

Interesting video on the double slit experiment which reverses "waves"
back to "particles".
I wonder how long before the books are changed back to the thoughts of
Newton and possibly my proof with respect to particles? Its a shame
that the professors on the physics
forum are still in a pattern against change or just not up to date in
the absence of a new up to date book. Of course it will take much
longer for the ham community to reconcile themselves and it may take a

new generation to adjust.
And a bit longer for QST and Radcom as they have a back log of
articles with respect to soldering connections on coax, morse code key
design and push pull tubes used in radios!
I am extremely happy regarding the helical spin shown which I
determined as a scalar reaction to the rotation of the Earth as it
gives more credability to my position that it is one of the two forces
that make up the Standard Model.(see unwin antenna page) as well as
the notion of tipped verticles to reflect same

Do you have any web references to gridded cavity antennas?

My intuition says your statements are correct. It is likely not wrong.

Thanks.

A good source is the paper from which I posted a few "fair use" clips, and was published in the Sept 1979 edition of the IEEE Transactions on Broadcasting. I'm not aware of any web link to it, and it is a copyrighted work. But probably your local public library would be able to access it through inter-library services, and provide you with a copy.

This design was developed by Harris Corporation, and has evolved/ improved over the years especially in the crossed-dipole element used to excite the cavity.

The design is now available through several manufacturers. The first link below shows a description of it from the 2004 catalog of Dielectric Communications, who bought the design from Harris. The picture shows an array of 12 layers of 3-around cavities that was built by Harris as a master FM antenna (9 stations) for the Senior Road Tower Group in Houston.

The second link below shows the measured axial ratio for an omnidirectional version of the antenna.

Very interesting article. Ofcourse I have only scanned it to get the
gist and will have to get a print out to study in depth.
It would appear that the subject is thermo dynamics and the transfer
of energty.
Popular thinkinking is that heat is created by the rapid occilations
of the constituent atoms
and thus one would expect that the constituent atoms would creat heat
which would be retained. My posture is that particles come and go and
where the energy or heat is carried of by the charge that the particle
carries Thus the more efficient the less energy required
to provide the eddy current grooves which occur only when there is
element resistance.
When the resistance is only the radiation resistance essentially less
heat is retained by the
element thus it stands to reason that the element becomes stable with
respect to temperature. As I have stated before the maximum efficiency
is when the input energy is applied to the particles alone where the
element resistance is zero a point that appears unattainable. So the
problem that hams have is to have a very low impeadance for maximum

efficiency which then is a matching problem divorced from the antenna mechanics. The article thus has incorperated a very efficient tuning method OR he has cut off the energy supply where as the energy applied at the radiator is not the same as the
applied system energy.The big change in the perception of particles is that they are not part of the element where it would be part of the boundary equation.The element has external particles with minimul energy at all times and where with a time varying field added
is a continual energy flow that carries away the applied energy via the displacement current
as shown on my page. This article will provide some interesting reading during the next few weeks after I get a print out.

Hello Joel,

As with many questions, the answer to the temperature rise method can
be "yes" or "no".

For this discussion I assume an antenna as a device or system to emit
radio waves to certain directions. Mostly designers try to maximize
radiation intensity over electrical input ratio, or total radiated
power over electrical input power.

For situations where obstacles are wavelengths away from the antenna,
temperature rise can be a means of evaluating antenna efficiency. I
once used temperature rise to accurately measure efficiency of a high
efficiency RF amplifier.

In cases where obstacles are very close to the antenna, just
determining temperature rise of the metallic structure being the
antenna does not satisfy me. You will know the dissipated power inside
the antenna, but not inside the obstacle in the reactive field. When
this obstacle dissipates 90% of the electrical input power, overall
efficiency will not be high.

By using the temperature rise of the antenna only, you will notice
higher efficiency when the (loop) antenna is closer to an obstacle
(for example a thick wall). In case of a loop, the Q-factor drops,
resulting in less reactive currents, hence less dissipated power in
the loop and tuning capacitor. Of course more power is dissipated in
the wall.

When the antenna is close to metallic structures with certain geometry, the real efficiency (so Prad/Pelec) may increase. The large structure may extract energy from the loop and reradiate it (instead of converting into heat). The extraction of energy from the loop results in lower Q-factor, hence less heat loss in the loop and tuning capacitor. Theoretically spoken, the temperature rise method is a good one.

How will you relate temperature rise of arbitrary structures to dissipation? If this question remains unanswered temperature rise method will also not solve the antenna efficiency question.

Regarding temperature rise methods in general, it is good way to find where losses are and whether it is worth to do some redesign to lower losses.

Best regards,

Word to the wise
When looking at the boundarylaws with respect to statics we are
looking at an "instant"
of time where all is in a state of equilibrium and in a state of
balance. Because we are looking at a two dimensional form we can
ignore the mass of the particles as they are so small we can't measure
them so we view them as passive. The same would be true if we took
the step of adding elements along with the particles ie they would be
passive.
But there is an important point here in that it is a two dimensional
boundary and by adding a elemnt we are transforming it into a three
dimensional, thus the addition of elements or radiators will have an
effect on equilibrium or balance. Thus if elements are added they must
be in equilibrium and balanced which requires that the additions must
not upset
equilibrium of the whole package PLUS the between the constituent
parts. When we add a time varying field to the package then the
elements must be the length of one period or one wavelength since with
the addition of the two vectors(gravity and rotation) supplies a
equal and opposite force to the radiator in response to the lifting
and accelleration to the multiple particles which creates vibrational
movement on the radiator. In other words the elements and the static
particle change from passive to active thus requireing non fractional
wave length. If we are to look at energy in equals energy out
equations mechanical reaction forces must be counted as with applied
and displacement current.

A thermal camera is NOT a good way to do calorimetry. It's a fine way to look for hot spots. Here are some of the potential problems: 1) the thermal camera converts long wave IR brightness to temperature using some assumptions about the emissivity of the surface; 2) convective and radiative losses to the surroundings will change the surface temperature; 3) surface temperature may or may not correlate well to dissipated heat.

It's an RF device, so the physical distribution of the power dissipation will be different than with DC. In a classic substitution RF power measurement, a lot of effort is made to try and make sure that the thermal properties are identical for the DC and RF dissipation cases (well defined broadband load that is physically small, etc.).

In the subject case here, think of this: say you had a 2cm diameter copper bar and you run 100 Amps of DC through it. The current is distributed evenly, as is the power dissipation. Now run 1 MHz RF through that same bar. The skin depth is about .065 mm, so virtually ALL the RF current is contained within a layer less than 1/3 mm thick. That's a very different heat and thermal distribution (sort of like the difference between putting that thick steak in the 200F oven and throwing it on the blazing hot grill).

One can calibrate for all this, but, still, it's tough.

A better way to do this measurement is to put the antenna in a suitable far field test site, accurately measure the power flowing into it, accurately measure the power flowing out of it (e.g. E & H field strengths in the far field)

Now, finding a suitable site is difficult, particularly at lower frequencies: you want to be "many" wavelengths away from the ground, for instance.

How about hanging it from a balloon with a battery powered transmitter (or receiver: I assume nobody is claiming that reciprocity doesn't work) and have the field strength detector also hanging from a balloon.

With some feedlines and frequencies, feedline radiation can become an
issue. For example, using 4" ladder line at UHF.

I think his method, especially for physically compact antennas and
feed systems which tend to have very low radiation resistance at HF
frequencies, is a great check on theoretical calculations. There has
to be a meeting point between mathematical models/NEC and reality and
he is working at one such point. There are of course other points too
(e.g. near field and far field measurements).

Tim.

Many types of noise certainly are predictable and real-world noise blankers do take this into account. They are not usually designed academically but to deal with specific issues.

e.g. Ham radios made in the 70's and 80's often had truly excellent noise blankers to prevent the Russian Woodpecker from blowing our ears off. I know you are talking about "subtracting" but for the common HF modes, blanking can be incredibly effective too.

I think that the emphasis on good blanking has died off since the 80's as the Woodpecker became less troubleseome then disappeared.

There are modern noise-rejecting "smart speakers" that auto-notch heterodyne whistles and some regular emission noise patterns etc.

The VLF experts often use a separate "noise antenna" which is phased, scaled, and then subtracted off the received signal.

Agreed -- the controversy comes into play in that he ends up computing
electrically-small loop antennas as being upwards of 70-90% efficient, when
everyone "knows" that such antennas are typically <<10% efficient. He even
goes after Chu/Wheeler/McLean/etc. in suggesting that the fundamental limits
for the Q of an ESA are orders of magnitude off (slide 47), and that's pretty
sacrosanct terriority (see, e.g., www.slyusar.kiev.ua/Slyusar_077.pdf -- even
the Ruskies buy into the traditional results :-)).

Hence, while I don't really have the background to know precisely how much of
what Underhill promotes is true or not, it's definitely intriguing to me, and
I'm looking around for various rebuttals by those more skilled in the art than
I am.

One link I found: http://qcwa70.org/truth%20and%20untruth.pdf (but this was
written before the PowerPoint presentation I originally linked to).

Hi Jim,

Thanks for the thoughts; I hadn't thought of many of the additional loss mechanisms you mention.

If you're just looking at surface temperature (i.e., with a thermal camera), will it take more or power at 1MHz to obtain a given surface temperature increase than at DC?

At DC, since you're heating up the entire bar, and the only way for the heat to go is up "out" to the surface... I'm thinking... less power is needed for a given rise?

That would certainly then overestimate antenna efficiency.

I can't see how the external fields come into it! That would
automatically be within the two vectors that supply acceleration, this
would be measure by the skin depth created by the displacement
current. The accelleration of charge is a constant dependent on the
conductor used. Where the particle goes when acceleration stops i.e.
after leaving the boundary is of no consequence.This would be seen in
the oscillation losses of the radiator
in the same way as with a pendulum

If you dont understand external fields then you dont understand
Maxwell's equations at all. Maxwell is all about fields. This pretty
much means you havent had a clue about anything you have ever said

about antennas.

Jimmie

Jimmy
I am referring to the boundary laws which is energy in versus energy out.
Maxwells laws finish with the completion of acceleration of charge.
The boundary laws are covered by this action and reaction per Newton.
The particle that is accellerated is the smallest known with respect to mass and we know that it is accellerated to the speed of light which is known for any particular medium.
Thus knowing the energy supplied we must equate it to the ejection vector applied to the particles and the reaction force applied to the radiating member.
NEC computer programs do just this and for such equations produce arrays where each
element is resonant and tipped to oppose the two vectors of gravity and the rotation of the Earth by supplying the array only where it is in a state of equilibrium and all elements are resonant as a result of the initial two vectors. The NEC computer programs do just this when applying Newton's laws which are not mismanaged to reflect planar forms.
Again I state that Newtons equations account for all vectors involved in radiation and does not in any way reflect the fields that are generated beyond acceleration and how the particles are dispersed beyond this point. This way it represents all types of radiation that the radiator is capable of and likewise makes it sensitive to all that is thrown at the receiving end ie H,V, cw, ccw signals e.t.c. and all the rest that is thrown at it which it converts to a useable current signal for the radio.Now if you are still in a state of flux as to the use of equilibrium in all the laws of the Universe then you are still spitting into the wind.

Hi Joel,

Your source is thrashing against a number of conventions that he has
disproved by relying on Schopenhauer - what a wheeze! This is the
same argument that "revolutionary" thinkers appeal to forgetting that
their theories can be dismissed by the same mechanism.

Let's examine this heuristically (irony there). Two observations
provided by your source raise the temperature of
1. a can by 100 deg C with 100W;
2. a tube by 100 deg C with 150W.
Heat is always concerned with mass and surface area, and heat transfer
is expressed in Watts per square Meter. Temperature rise is expressed
in joules for specific heat capacity and mass.

The two examples provided by the source differ by -50/+100% in heat
transfer. How does this impact the development of a "new theory?"
Let's revisit the two examples normalized to transfer:
1. the can exhibits 127W/mï¿½
2. the tube exhibits 57.7W/mï¿½
Such discrepancies are meaningless? I assume so, because the source
doesn't respond to answering them.

There is, of course, a very simple explanation that heuristics reveals
in specific heat capacity (a term completely absent from the
discussion of heat in a radiator).

Let's consider the nearly 1m loop with a heating wire inside -
curiously unspecified for such a "scientific" and unbiased report. It
is, in fact, an 18ga wire of 80% nickel and 20% chromium (yes
nichrome) which by the current supplied heats up to 550 deg. C. These
details must be immaterial to the original source that ignores them.

Could one imagine a heater wire at 550deg. C heating the outer tube by
100 deg C only? Well, let's consider that light bulb in the can that
exhibits double the heat transfer. It's filament is running at
somewhere between 2200 and 3000 deg C for the same temperature rise.
Nature must have some curious law of heat plateau in this "new
theory."

If we were to rely on heat reportings alone to carry the logic, then this vast wobbly range of -50/+100% reported values is not very compelling. Intuition is often appealed to in these pages (some call it heuristics); and it would seem that the heated wire, with 150W and supporting 550 deg C would eventually melt the antenna components. Where else is the heat at that temperature going? It is entirely contained by the copper tube. Yet our source does not reveal this - and ironically points out that would be the fate if RF could raise temperatures.

However, temperature is NOT power. How much power would it take to raise that specific 83 cm diameter looped 10 mm copper tube 100 deg C? The answer is 2.16 W-Hours. The 550 deg C hot wire is running at 150 W continuous and only pumping up the temperature a paltry 100 deg C. That is pretty pathetic.

The answer is ALSO 7800 W-Seconds. Clearly 150W for several seconds wouldn't make a noticeable heat boost. That is pretty pathetic too.

Obviously heat rise is a product of time (the term "rise" demands this) and yet throughout this source's "scientific" and unbiased report time measurement for these heat readings are wholly absent. How many in this forum recognize the duty cycle of a typical QSO in this? How many antenna failures follow from heat, how many QSOs still suffer from poor efficiency?

For those who care, the formula is simple:
Q = m ï¿½ C ï¿½ (Tf - Ti)
where
Q is joules
m is mass in grams
Tf is final temperature (K or C)
Ti is initial temperature (K or C)
C is specific heat capacity in
J/(K ï¿½ g)
or
J/(C ï¿½ g)
and for copper is 0.39

For comparison, water's specific heat capacity is 4.18, more than ten times higher and thus more power is required to raise water that same 100 deg. and this is why water is used in radiators. Mineral oil runs about half that (and folks struggle to obtain transformer oil for their dummy loads when water is superior).

An aluminum tube at 0.90 is thus going to run cooler than copper when we put a heater wire inside (for the same, unstated, time interval).

Given the inordinate number of facts missing, undisclosed time intervals, no discussion of heat capacity (in a heat report) and the

obvious cynicism cloaked in "heuristics, science, and unbias" -
further reading on other topics has every chance of being equally
blighted.

To put icing on the cake, I am astonished that the original source can
only eke out low 90s percent efficiency in the 20M band! To employ
the original source's arguments: Put 450W to that sucker and tell us
where the 20 to 30W were lost. As it takes only 2W-Hr to raise that
antenna 100 deg C, that air cooled dummy load must be boiling rain and
burning fog.

--- and then again, maybe I did the math wrong.....

Source record: 10538

On the surface, the method seems reasonable. However, remember that heat (which is energy) is removed by three mechanisms: conduction, convection, and radiation. And the temperature rise depends on the rate heat is lost through these three. The effectiveness of each mechanism will be different for each part of the antenna structure. So to realistically judge the temperature rise due to RF compared to DC, the two have to be distributing heat to the same parts of the antenna in the same amounts. This isn't a trivial task, and no care was taken to do so.

An additional problem with the method is that no attempt was apparently made to actually measure the amount of RF power being applied to the antenna. So knowing the amount of power required for equal heating would be insufficient for determining efficiency even if it could be accurately measured.

That the method fails is demonstrated by the results. The author concludes that the sample antennas have much higher efficiency than known and proven physical laws predict and countless measurements have confirmed. He's proposed "correcting" NEC, which applies known and proven physical laws, to agree with his "heuristic" measurements based on poor methodology and no direct measurement of efficiency such as field strength. This is a common theme of junk science, and firmly identifies this work as being in that category. A search for flaws in his measurement methods is much more likely to be fruitful than searching for fundamental flaws in NEC and current physical laws.

But I'm sure that some of the same folks who swallow homeopathic remedies and arrange their lives around astrological predictions will replace their 160 meter towers with tiny wire loops. P.T. Barnum's famous observation is still true.

> Mike g0uli

Mike you know and I know that the double split experiment was
interpreted as evidence
that radiation is created by a wave and not a particle as in quantum
mechanics. This being in opposition to the thinking of the masters of
the day . The descision made went far beyond the duallity stage when
they made this interporetation. Now it is called the infamaos
experiment as they have now identified the initial observations as a
result of particles. To my knoweledge there is no books available for

University students to get up to date as physicist are reluctant to change or to admit errors. Until this is done students will continue to remember what the books state to pass their examinations. A long time has passed since the time of Maxwell and the books still force Universities to stick with fields and waves where nobody can procede in the search for truth as we do not know the mass of the waves or the energy mechanism of the revolving door of such. This group who have been taught to memorize what a professor states and not to question by first principles of what is stated then they all know what to encircle at exam time from a to c which is what the professor said and has nothing to do with reality. It is not surprising that Einstein failed in his quest to describe the Standard Model as he was building on the shoulders of those that preceded him on the assumption that they were free from error. Now with computers we have a tremedous amount of formulas that are built on errors which leaves huge gaps in understanding and the number of constants and predicted particles to make sense of all these manufactured formulae based on error. It is not surprizing that physicists are getting away with all this tripe by stating that all those outside the discipline are all crackpots as they have had no instruction on their version of the discipline of mathematics. Now we are all paying for the multi million CERN project that is intended to break the smallest particle known to obtain a lesser mass so the speed of light can be exceeded.As for the Higgs field
predicted by their wierd forms of mathematics it will be found as a constant squared divided by the mas of numourous unfound but predicted particles!

One wants to be careful about "Q" and Chu, etc. If you haven't
actually read the paper, you might think that Chu is talking about Q as
in filter bandwidth (e.g. center frequency/3dB bandwidth), but it's not.
It's the ratio of energy stored in the system to that radiated/lost.
For some systems, the two are the same, but not for all.

And one would need to be careful about when you've reached thermal
equilibrium (if ever)

I read it well over a decade ago. I like to think I've learned a fair amount since then, so I should probably go back and do it again some time...

I had McLean as a professor as an undergraduate -- he was already ruminating about Chu not having the full story back in the early '90s, several years prior to his (apparently pretty regularly referenced) paper on the topic on '96
(http://www.physics.princeton.edu/~mcdonald/examples/EM/mclean_ieeetap_44_672_96.pdf).
(He was also a fan of Goubau antennas and wanted me to help him figure out just how they worked... I never managed to contribute anything of use towards that end and graduated and moved, but I did visit him a few years later at which point he told me it'd really been rather more difficult to figure out then he'd first thought. Harumph! I do think it's cool that it eventually ended up on a cover of a book:
http://www.amazon.com/Electrically-Small-Superdirective-Superconducting-Antennas/dp/0471782556)

> It's the ratio of energy stored in the system to that radiated/lost. For

Something like... it's exactly true of a simple RLC network (2*pi*total stored energy/energy lost per cycle)... but one can concoct fancy, higher-order networks where it isn't exactly correct?

> boundary enclosed static particles in equilibrium is illegal.

your whole concept is malformed. if the 'static particles' are in
'equilibrium' (i.e. not moving) and then you add a time varying field
the particles are going to start moving and won't be in equilibrium
any more... assuming of course the particles are charged or have a
magnetic moment.

> This is in opposition to what the books say.

which books. quote titles and paragraphs and what you think you
oppose in them. i have given you my quotes as to why it is not
necessary to add a time parameter to gauss's law and you ignore it.

> My whole theory lives or dies on how this is resolved. Nobody will
> provide technical details as to why this is illegal.

then you better start hunting for a new theory. i have provided you
formulas in the past and you have ignored them... personally i don't
think you even understand the concepts and have probably ignored me on
purpose just so you can continue to blather on to get more attention.

As i said before, if you do not accept the laws of physics then we
cannot debate physics
Probably the best thing to happen for both of us! You can take a horse
to the water trough
but you can't make it drink. Especially when it puts his arse to the
front and lets loose with hot air.Your last statement shows all who
you are and what you are. Free speech can have its price.

Once again, you throw insults when the discussion does not go your way.
I'm not sure you even know who you replied to.

As far as folks not debating you, first present your position in a clear
way with the appropriate math and equations. Allow others to try to
understand your way of thinking. To date, you have not provided the kind
of detail necessary for the kind of debate you would like.

As I said before, just adding "+t" to an equation does not make it
right. If I've interpreted your position wrong, then it is because you
have not clearly expressed it.

The ball, as it has always been, is in your court.

It is not a matter of accepting the laws of physics. It is what you do
with/to them that may be the problem.

If you want to discuss physics, present your case the way those knowledgeable in the field would do.

xxxxxxxxxxxxx
Well you can discuss your ideas on physics with David. There are also
some on the group
who obviously understand classical physics. So you have a choice of a
sensible discussion
on physics as well as a discussion of your idea of physics. I await on
the side lines with interest to see what choice you make!

or, an antenna, for which the approximation of an RLC is only true in a
limited frequency range.

There's a fairly good literature out there about the limitations of Chu
(after all, he was only the first shot, and modeled it as a single
spherical mode). Harrington was the next bite at the apple, and then
there's a whole raft, particularly when you get into superdirective
arrays or antennas/systems which have non-reciprocal devices in them.
R.C. Hansen and McLean (as you note) are others. When you start talking
about antennas directly coupled to active devices, that's another thing..

Consider that the low impedance of a small loop is a good "match" to the low output impedance of semiconductor devices in RF applications.. Now you've got a reactive load hooked to a reactive source.

Hmmmmmm.

I thought that you claimed Maxwell is STATIC.

How can anything static accelerate something?

Sorry, I should have spelled it "accellerated", which is probably
another new thing you have made up. So if that's what's going on here,
I apollojive.

I'm pretty sure that it is not so easy to just measure power in, heat
lost, and assume that everything else is being usefully radiated.

I think that after you've modeled and then built an antenna, that heat
loss and temperature measurements are valuable to determine if the
assumptions you put into the NEC model regarding loss etc. are correct
or not, and where you need to improve your model, especially of
materials like dielectrics.

Even the heat loss measurements require some fairly heavy modeling
just to convert the IR camera images to actual watts per square cm.
Think it's purely radiative? Sometimes yeah, but make the wrong
assumption when really it's convective and you can be off by a factor

of ten to thirty.

Tim.

Mike you know and I know that the double split experiment was
interpreted as evidence
that radiation is created by a wave and not a particle as in quantum
mechanics. This being in opposition to the thinking of the masters of

the day . The descision made went far beyond the duallity stage when they made this interporetation. Now it is called the infamaos experiment as they have now identified the initial observations as a result of particles. To my knoweledge there is no books available for University students to get up to date as physicist are reluctant to change or to admit errors. Until this is done students will continue to remember what the books state to pass their examinations. A long time has passed since the time of Maxwell and the books still force Universities to stick with fields and waves where nobody can procede in the search for truth as we do not know the mass of the waves or the energy mechanism of the revolving door of such. This group who have been taught to memorize what a professor states and not to question by first principles of what is stated then they all know what to encircle at exam time from a to c which is what the professor said and has nothing to do with reality. It is not surprising that Einstein failed in his quest to describe the Standard Model as he was building on the shoulders of those that preceded him on the assumption that they were free from error. Now with computers we have a tremedous amount of formulas that are built on errors which leaves huge gaps in understanding and the number of constants and predicted particles to make sense of all these manufactured formulae based on error. It is not surprizing that physicists are getting away with all this tripe by stating that all those outside the discipline are all crackpots as they have had no instruction on their version of the discipline of mathematics. Now we are all paying for the multi million CERN project that is intended to break the smallest particle known to obtain a lesser mass so the speed of light can be exceeded.As for the Higgs field
predicted by their wierd forms of mathematics it will be found as a constant squared divided by the mas of numourous unfound but predicted particles!

Hi Art,

The problem with many of these discussions is that there is a mathematical, perfect model and then the real world. The real world is imperfect and full of minute flaws and discrepances that tend to be smoothed over and cancelled out at large scales, but have very real effects at molecular and smaller dimensions. The mathematical models will work just fine at making predictions in the every day world we are used to, but tend to fail when scaled up to the truely immense or down to molecular levels. This is not necessarily a fault of the maths or the theory, it just means that not all the factors that affect the calculation are known or accounted for.

People have indulged themselves in calculating PI to umpteen decimal places. What is the point? By the time you get to 100 decimal places you could probably plot a single atom anywhere in the known universe to within a fraction of its diameter. A third displayed as a decimal fraction comes out as 0.333... but we also know that the 0.00...1 does not actually exist. So there is a flaw in the way that a fraction can be displayed at a very basic level in mathematics and this does cause errors in calculations. These can

be accounted for by using different methods to arrive at the correct answer, but the calculation is a lot more complicated using decimal arithmetic than just adding 1/3+1/3+1/3 and arriving at the correct answer of 1.

So the answers you get seem to depend on the methods you use. The skill is in deciding what is the most appropriate method that gives a best match to the observed results and also gives the most accurate predictions for the results that might be observed in future experiments.

Science creeps along step by step improving accuracy and developing models that more nearly match the real world with each generation building on the foundations of those that have gone before.

Maxwell's equations have served pretty well and I'm personally not convinced that adding a time term to the equations is necessary to improve everyday predictions of antenna performance. You, of course, disagree because your antenna designs are supposed to generate RF in a different manner to conventional designs. I don't have a problem with that at all, you have to use the most appropriate tools you have to support your ideas. But novel ideas are always a hard sell and it is always an up hill struggle to overturn an established orthodoxy, no matter if you are right. Unfortunately it takes time for new ideas to become accepted. Most of the Nobel prize winners seem to have waited many years before their achievements are acknowledged. It seems a shame that they win a prize at the end of their careers when one wonders what they could have achieved with the additional funds if they had been available at the peak of their abilities. Such is life.

Incidently, I'm a great fan of CERN and the fusion projects. I know they are currently seen as huge white elephants and an unnecessary drain on the economy, but I believe that they are necessary for future science and securing a viable means of sustainable power generation. Finding a Higgs particle may not have a direct effect on your everyday life, but it does have enormous implications for the future of physics and pedictions about what may or may not be possible in the future.

Regards

Mike g0uli

>
> Tim.

But Tim Maxwells equations are accepted every where and appear to be
valid.
Because of this antenna computer programs are based on these
equations.
Thus when a optimiser is added the program can change the input to one
that satisfies
Maxwells equations. Assuming programers did a good job in focusing on
the Maxwell equations then we are provided with an array that meets
Maxwells equations.
What more can we possibly need other than a program that accounts for
all forces involved for the generation of ALL radiation available for
communication use that can be propagated
If we have a distrust in the programers or in Maxwells laws then one
should ditch the arrays
supplied by an optimiser and find what some refer to as a "new
technology." Until one comes along we first have to delegitemise
Maxwell and we have been unable to do that!
Maxwells equations can be justified via all known laws in physics
including making static laws dynamic. and adhering to the absolute
requirement of equilibrium with respect to physics laws. The main
problem we have is misinterpretations we add by using lumped loads etc
which Maxwell never included same. This also is the case with the yagi
where
Maxwell never supplied anything with respect to planar or even a
stipulation that elements must be straight, parallel, resonant,
etc ,only EQUILIBRIUM. where all data can be placed on one side of an
equal sign and where on the other side MUST equal zero..
So we dance with the one that 'brung' us
Regards
Art

Art's antennas radiate from the ends. There are charges but they are not
static. Gauss flux is for staic charge. If you add "+t" the flux will be the
oscillating flux.

G3LHZ went to conclusion that antennas are source/sink. The same did Art. Am
I right, Art?

In such case particles (electrons?) oscillate also. But the waves consist of
oscillating "particles".
Maxwell's waves consist of rotating oscillations, Art's are longitudinal.

This is great! My theory has always been that RF is like tiny little turds that fly off your antenna. And if you spend too much time transmitting and too little receiving, (after all, you antenna has to pick up little turds too) your antenna will get smaller.

I've already been ridiculed

I got beat up after the last Ham club meeting becasue they think I'm making fun of them and they hate my turd theory.

So any day now, I'll be the new antenna master. Stage three, here we come!

PS, the way a beam works is that the little turds hit the other elements and bounce back, making the signal more directional.

It's all accounted for in Mike's crappy antenna theory.

he wants to take gauss's law for the flux through a surface containing
charges and add a time dependency to it. the argument against that is
that the equation is already good at any time, it doesn't need to have
a time dependency since it is true at any instant anyway.

oh, so you understand art's concept of 'static' and 'equilibrium'
enough to argue that side of it?? how do you 'equilibrium' and
'static particles' unless they aren't moving? equations please, show
your work, extra points for deriving how his magical levitating
diamagnetic neutrino fits into the equations. please, we need someone
who can fill in the gaps that art can't seem to do.

the planar designs are a _result_ of maxwell's equations plus some
basic mechanical engineering considerations. coupling between
parallel wires or tubes is predictable and easily controlled by
adjusting length and spacing, all in accordance with maxwell's
equations, to make a family of easily designed and constructed

antennas. are they the ultimate, no, i quoted you a book probably a couple years ago where an optimizer was used and came up with planar elements that were more like a wavelength long but shaped like a cross section of a bowl. a 3d optimizer can do other things, but then you loose some of the important characteristics of the Yagi-Uda arrays, like the control of polarization and ease of construction. and yes, you can use maxwell's equations to model lumped elements, you just have to model them on the appropriate scale with a program that handles very small segments.

No, I don't understand Art's concepts, who could? But I do know that equilibrium is not generally defined as "not moving". In fact motion is not even mentioned. Look it up. I did.

And I have no argument with the current state of affairs within Electromagnetic Fields and Waves, and no desire to argue it, either. It was a big enough pain in school.

What makes you think I was arguing his side? I couldn't disagree with him more.

Agreed on the use of various equations but they are not the maxwell
equations

 coupling between
> parallel wires or tubes is predictable and easily controlled by
> adjusting length and spacing,

Nothibg wrong with the yagi but it is not in accordance with maxwell

all in accordance with maxwell's
> equations, to make a family of easily designed and constructed
> antennas. are they the ultimate, no,

Yes the yagi has a lot going for it

i quoted you a book probably a
> couple years ago where an optimizer was used and came up with planar

> you can use maxwell's equations to model lumped elements, you just
> have to model them on the appropriate scale with a program that
> handles very small segments.

No lumped elements are not included in maxwells equations
You can add them ofcourse but then they are not maxwells equations.
There are benefits to totally adhering to Maxwell equations without
alteration.
The books say that radiation is not understood but the equations of
maxwell are correct as they are, but when altered they are not
Maxwells laws anymore. So using maxwells equations without alteration
is building on a ultimate truth
We are now able to build smaller volume antennas because we are
adhering to equilibrium
which means we can compress the array into a smaller volume and still
retain equilibrium.
With only the Yagi at hand we have been unable to build the smaller
antennas that are not possible with the Yagi design.Now we can follow
maxwell to the letter and produce an array
that is sensitive to all that is thrown at it which many will seem as
a step forward while we have not deviated from Maxwells laws one bit.
Now maybe somebody will come along and advance beyond this point
knowing that he is building on truth because maxwell has accounted for
all forces involved in a process even tho at this time we do not know
what it includes. Now you may not like the aproach using Gauss but
that is o.k., because you can
still use Maxwell as it was intended instead of the alternative
aproach of the Yagi.
So the more we advance by building on truth the better off we are all
going to be even tho
we may not advance in knowing all that is happening in the process. A
case in point is the helix antenna, We now can compress the helix to a

zero pitch and by using a twin wire the antenna can be brought in equilibrium noting at the same time we have cancelled the lumped loads in accordance with Maxwells principles.

However he gave you the right answer to the question you asked.
There is no one best coax!
Are you just using it for receiving or transmitting as well. Typically
you don't find either of those cables used in ham stations, except to
feed Beverage receiving antennas.

I use a lot of "flooded" RG-6 with compression connectors for UHF
receiving. I use RG-8X (foil with shield) to the 40 meter, half wave
sloping dipoles. It's fairly rugged, very flexible, presents a low
profile to the wind and doesn't weight a lot. Its power handeling
capability is a bit low, but I haven't blown any out...yet, unlike
CNT-240.

>>> they'd say 'hie me to a research lab, if not an actual
>>> nunnery'. :)

Then perhaps you should purchase coax elsewhere?

>>>Not that you're wrong, but if you want a single general

RG-6 is foil plus braid and it doesn't get much better than that.
However for HF my choice would be RG-8X (with foil plus braid- it
comes in many forms) although I use LMR-600.

Good luck,

Roger (K8RI)

I have 5 runs of RG-6 (foil plus braid) running in a conduit with 2
LMR-600 cables carrying 1500 watts of RF at HF. I also have 3
CAT6 network cables in there. None of them hear the others.

>not to be expected to do the same for HF.

It's the shield, of which the braid is only part. Only if you are running the RG-6 with other HF cables *might* you find a problem. As I said above, I have 5 of them in the same conduit with cables carrying 1500 watts of HF RF and there is no cross talk. That thin foil is just fine at HF as well as UHF as long as it's not carrying substantial power. Where you really need the extra shielding is at very low frequency,or very high power. They do make quad shield RG-6 for receiving, but it's not a cable for high power transmitting. I'd not put more than 100 watts into RG-6 of any configuration.

73 and good luck,

Roger (K8RI)

Compression fittings. Easy to install, strong, water proof, and about
50 cents each.

>
>A friend brought some Radio Shack screw on PL-259 connectors that work fine
>with it, but they are $6 each in the US, and unavailable here.

And a waste of money.
The problem with the compression fittings is you need a compression
tool to install them although a pair of the "duck billed" vise grips,
or even pliers could be adapted to do the job. You only need hold the
front and back of the connector and then push the pack part with the
seal into the front part...a distance of maybe 1/8" (4mm) . The
commercial tools are kinda pricey, but you can make one up out of a
pair of pliers and a bit of ingenuity.

Well said, Roy. I just purchased 2000 feet of "RG-6" coax. My main goal was that I needed hundreds of feet of flooded coax with (good shielding) that I could afford. The Commscope CATV aluminum foil/ braided coax that was available on eBay fit my needs perfectly.

I'm feeding my remote Beverages with it, as well as running medium power to an inverted L on 160. Works great.

I'm convinced that no other coax at any price would have worked any better.

The turds oscillate in antenna and if the VSWR is low they fly off. As they
oscillate some of them come back but not all (Stokes drift - mass
transport).
>
> So any day now, I'll be the new antenna master. Stage three, here we come!

The real masters are in the secret centres. H. Wabing wrote: "Shielding and

The dipoles directional pattern are the result of the interference of waves
from the two ends. The truds oscillate. It is wave.
>

> It's all accounted for in Mike's crappy antenna theory.

Civilian antenna theory.

New here eh, Joe?

Homie don't play that.

I think it has something to do with the old saying" If I have to explain
it to you, You aren't capable of understanding it."

Not at all. Just trying to get Art to explain himself. If he really
wanted to discuss his ideas he had the opportunity.

However, his responses make it clear he really has no desire for a
constructive discussion.

> who can fill in the gaps that art can't seem to do.

I totally agree, Some body is needed to fill in the gaps that art is
unable to do

First, one has to explain equilibrium
Second, one has to explain the boundary laws
with respect to statics
making note that equilibrium must be
in place
Third, one has to make the field dynamic by
providing a
time varying field
Fourth, one has to add formally passive items
into the boundary
so that the entire dynamic field in
place is in a state of equilibrium.

Note: you may add radiators to the inside of
the boundary in the first
instance, but in the second instance
when you make them active
then they have to be both resonant as
well as a wavelength long

by firtue of also being a period One
can then applyMaxwells equations for radiation to the
final arbitrary boundar

Who ever manages to explain the above must
point out that the particles
that are ejected from inside the boundary are
immediately replaced fresh passive particles
that are outside the boundary looking for a diamagnetic surface to
reside upon where, in this instance, is aluminum or copper or any
other material that is diamagnetic such as the radiator

Who ever takes on this task of explaining the above to this
group so that they understand most assuredly has my respect .

Ive never seen Art apply Maxwell's equations. If he had really been
applying Maxwells equations he would have know that contra wound dummy
load he ranted about for so long would not work.

A slinky does "work" when it is contra wound .where a lumped load
cancels the other lumped load as Maxwell did not provide for them in
his equations,only distributed loads.
If you read Jasik's book he takes care to contra wind the coils, same
as one would do with traps. The so called slinky that one purchases
today are NOT contra wound
Jimmie, the group is looking for somebody who believes they
understand physics to explain what I cannot and you obviously perceive
yourself as an expert!
"Go for it!

Not quite. "The group" probably just hopes someday you will make
sense. Will that happen? You are sloppy and undisciplined, and the
probability that you can develop the ability to be coherent is
extremely small. The least you could do is read your messages once
before you post them.

I seriously doubt if there is anyone here looking to have high school
physics explained to them.. Most already have that down pretty well.

You are entitled to your extremely judgemental interpretation but it is not necessarily correct!

An amateur is a person who is not a professional, a professional is someone who is paid for their skill(s). Nowhere does it say that either is competent or incompetent. Many amateurs are vastly more skilled than professionals operating in the same area.

Only this week NASA were impressed and enquiring of a UK hobbyist how he obtained such incredible pictures of the earth from 21 miles up when it cost them millions of dollars to to the what he had done for about $750.

(He'd put a common digital camera with some electronics and a simple radio beacon as the payload to a helium balloon which burst at 21 miles up and which then came down by parachute and he was able to locate it by radio DF. See http://news.bbc.co.uk/1/hi/england/west_yorkshire/8587749.stm . Now that is an amateur - hardly fits your idea of amateur does it :-)

Charlie.

I know people that have been quite obese and have dropped 150 or more pounds while out of my sight. Without mentioning they were up to anything so sinister.

I know people that have fought their weight for their entire lives and can do nothing about it, even with serious and severe medical assistance and being warned it will eventually kill them.

So obesity is a mixed bag, almost always very tough to deal with, and nothing for anyone to make fun of. I assume just making fun is what you were doing. Unless you're a total ass. At this point, I'll give you the benefit of the doubt.

I will reply about , but not in any way apologize for, what I wrote a
few minutes ago.

When you write a first line like what you did, you should expect that
some people will immediately go blind and respond harshly.

That is not an apology, I still think you may be an ass.

Hello,

Unfortunately for me, but lucky for you, I need to sell my lovely 27'
Coronado sailboat. She's really a beautiful boat, with a VHF radio,
stove, icebox, head, galley, can sleep 5, and lots more!

Please take a look, she's currently on eBay with pictures and a long
description, here: http://bit.ly/dAOa1O

Thanks a lot!

Boat: A hole in the water into which you pour money.

The two happiest days of a boat-owners life: The day you buy the boat
and the day you finally get rid of the damn thing.

I had a Coronado 25 for about 10 years....fantastic boat. Spent a fortune
on it. Enjoyed every minute. I have more money now that it has been
sold.... ;)

Incapable of recognizing sarcasm, or just looking for an argument?

I was replying to our good D. Stussy, who indeed has a problem with the word amateur, and seems to have issues with the obese.

I am an amateur radio operator in the classic definition, that of one who loves the activity, not in the much more recent corruption of the word - that of non-professional or shoddy.

Most very strange in a world where I can perform most activities much better than th eso called professionals.

Yes and yes.

FWIW, my son was engaged to one of the most stunnningly beautiful and
not-an-ounce-of-fat young ladies I ever met. She turned out to have a
not-so-stunning personality as we got to know her better.

It's a physical thing, I'm more interested in minds - and I'll take a
fat nice person any day over an evil thin one.

A couple recent comments:
1) An amateur is a person who is not a professional, a professional is someone who is paid for their skill(s). Nowhere does it say that either is competent or incompetent. Many amateurs are vastly more skilled than professionals operating in the same area.

2) I am an amateur radio operator in the classic definition, that of one who loves the activity, not in the much more recent corruption of the word - that of non-professional or shoddy.

Most very strange in a world where I can perform most activities much better than th eso called professionals.
---

pro -> does it for money. Implies that there is some (financial,reputation) responsibility for results

amateur -> does it for no money (e.g. for the love of the activity, see the Latin root of the word).

Proficiency, competency, or skill doesn't really enter into it. Although, an unskilled professional had better be a good salesperson, because otherwise, nobody is going to be willing to compensate them.

Lord Rayleigh was an amateur: nobody was paying him to do his work.

It's also true that a pro that has been in business (successfully) for a number of years is likely to be competent. (or they'd starve).

An amateur can get away with being incompetent for years without ill effect.

In some fields (Engineering, in the United States), there are some legal aspects to being "pro" aside from being compensated. To call oneself a Professional Engineer, one must have a certain amount of experience (6 years, typically) at engineering, have passed a couple of fairly rigorous tests, etc. so that you have a license. One could acquire the experience while unpaid, and certainly one doesn't get paid for the test, so one could be an amateur Professional Engineer.

I still haven't found enough time to be able to bring the MA5B back down to ground for a good look and put a good choke balun in line to see if the noise improves.

I do know that when I purchased the grease it did say its a conductive grease for aluminium. It didn't come with any instructions so I applied the grease as thick as I could to prevent any corrosion. It looks like using to much grease might be all or some of my problem. The only place I didn't put any grease was on the elements were the matching network connects to. I used clear silicon sealant for those.

As soon as I can find enough time I will post back with my findings.

Thanks

Hi David,

Protection is not often a product of liberal application.

>It looks like using to
>much grease might be all or some of my problem.

Hard to imagine. If you are clamping things together, the notion of
"too much" takes care of itself. i.e. You cannot have "too much"
toothpaste in the tube if you squeeze hard.

If, as you say, this is "conductive" grease, then clamping down hard
also brings electrical continuity and there is no issue of having "too
much" grease.

So, what this basically devolves to is: "did you apply enough
clamping?"

>The only place I didn't put
>any grease was on the elements were the matching network connects to.

Why?

> I used
>clear silicon sealant for those.

This has an acid base (depending upon the formulation being one of the
common, garden variety sealers) that sometimes brings problems of
corrosion. Again, this depends on the formulation.

However, the noise you describe is not one ascribed to grease in any
form, nor to sealants whatever their propensity is for corrosion.

Hi Nico,

Seeing the far field is a function of using 4nec2, not in describing
the wires (writing the code). This means there is a control button
you must activate to generate a view of the far field.

Perhaps someone who has experience with this package can help you with
that specific point.

3rd Baron John Strutt

During the time he managed his late father's barony from 1873 to 1879,
he did some research. The Theory of Sound was published in 1878.

Then, after he left the Cavendish Lab at Cambridge in 1884, he continued
his research at home.

For all I know, Cambridge didn't pay him either.. he was definitely a
"man of means" and sort of typifies the "gentleman amateur"

Antoine Lavoisier or Joeseph Fourier would be other examples. Both had
"jobs" that paid well and didn't require a lot of their time, so they
could spend their spare time and cash on science/engineering.

1001. Radiation patterns and loss of antennas operated well below resonance

Newsgroup: rec.radio.amateur.antenna
Date: 2010-03-30 22:43:05 UTC
From: Joel Koltner <zapwireDASHgroups@yahoo.com>
Message-ID: <%7vsn.154712$rq1.131442@en-nntp-02.dc1.easynews.com>
Source record: 10401

If I take an antenna that's resonant at, say, a couple GHz, and operate it well below that frequency (say, some hundreds of MHz), it's clear that for something simple like a dipole, its radiation pattern is the usual "bagel" shape that an "elemental" (infinitesimally short) dipole would give you.

But say I use something like a patch antenna that's designed for 2.4GHz and build enough of a matching network that it presents a 50ohm impedance to, say, a 70cm transmitter. Does the radiation pattern change much? Will it become so lossy (radiation resistance rapidly heading towards zero) that this isn't really a good idea in the first place? (I wouldn't be surprised if a patch antenna actually doesn't radiate much at all outside of the antenna's own resonances...) Or perhaps it's not possible to say, in general, what happens and one needs to perform simulations on a case-by-case basis?

I'm asking based on the thought that there are a lot of pretty nice, off-the-shelf antennas out there that were designed to be resonant (using, e.g., quarter-wave dimensions) at some pretty high frequency (2.4GHz being a common one, of course), and I'm interested in how viable it is to use these antenna for 2m/70cm amateur radio use.

Thanks for the input,
---Joel

Hi Joel,

Depends on your meaning of "much." Given the ad-hoc nature of your
goal (and the resolution of any S-Meter in those services): you
wouldn't be able to tell any difference at all.

>Will it become

Loss will be largely dictated by match, and the matching components'
and the radiator's Ohmic loss.

>I'm asking based on the thought that there are a lot of pretty nice,

Because they look cool? That will change fast when you add in the
matching accessories (and that doesn't mean fashion coordination).

The rule for any antenna is small - broadband - efficient: pick any two. You've chosen small, leaving you your choice, within reason, of one of the other two -- although as it gets really small, the efficiency choice gets less achievable. The lower the frequency, the more the patch will look like a capacitor, with lots of energy stored between the plates each cycle, and a small fraction of that being radiated. The large energy storage means high current, which means high I^2 * R loss and/or high loss in dielectrics due to very high E fields. This is the same basic problem you have with all electrically small antennas. You'll end up losing more and more in the matching network as frequency drops, too. If you do manage to minimize loss you'll end up with an exceedingly small bandwidth.

Expect the same pattern from the far-below-resonance patch as you get from a small loop or dipole.

Sorry, as Robert Heinlein (and others) said, TANSTAAFL (There Ain't No Such Thing As A Free Lunch).

But you'll probably be able to make some QSOs with it and, with the help of some mystical mumbling about equilibrium, photons, critical coupling, and reflected power waves, you'd surely be able to collect a gaggle of true believers.

More because they don't take up a lot of space. I realize that any reasonably small antenna for 2m (meaning: "fits in the palm of your hand") is going to be a compromise anyway, but if you can have a nice-looking antenna that performs as well as a rubber ducky, heck, I'll have it look nice too...

Thanks Roy, that's a great summary.

If I started from the vantage point of wanting to design a flat panel-style (patch-like) antenna for 2m (and let's assume narrow band is fine for the moment), are there any obvious starting points besides a big patch that's being operated well below resonance (let's assume I want my panel to be no bigger than 6"x6")? Just meandered lines are probably as good (and can be readily simulated in NEC :-))? (I've read Randy Bancroft's book on patch antennas and have a reasonably good feel for how they operate... although he makes it clear there's often plenty of empirical design involved too, particularly when you want to get fancy and achieve circular polarization by exciting multiple modes at once.)

It's a shame than Nathan Cohen has already largely cornered the market on overselling the potential of fractal antennas. :-)

Hi Joel,

I noticed your response to Roy you made reference to Chip and
fractals.

A fractal will work, but back then we learned the lesson of Chip's
carefully crafted problems he posed to us such that only his antenna
would fit into the box he specified:
"Show me your best antenna that fits into
0.1WL by 0.005WL by 0.05WL
with a CCW dogleg twist in the longest
dimension that is elevated
22.5 deg above the horizon
and my fractal will beat it."

So, in commemoration of that sort of criteria, what do you mean by
>...don't take up a lot of space.

Hello, all, and I think a wee bit of clarification is needed here:

Profession (n): One who engages in a pursuit or activity professionally.

Profession (adj, sense 1c): Characterized by or conforming to the
technical or ethical standards of a profession.

(Both definitions taken from Webster's New Collegiate Dictionary)

Now, in light of the above couldn't an amateur (not a dilettante, mind
you) radio person practice his/her craft "professionally?" Sincerely,
and 73s from N4GGO,

Hello, all, and back to the rear of the class for grammar/spelling. The
two above terms should have read "professional" vice "profession".
Sincerely,

Isn't deriving satisfaction and sense of accomplishment part of fun? It
is for me, anyway. I suppose one can do it and get paid, being
professional, and still have fun. So maybe I should clarify and say
"who does it for *only* fun".

Further the status of amateur doesn't imply the right of doing
> it less consciencious than a professional.

I don't know about that. Aside from regulatory requirements, as an
amateur one can do it however well or poorly one wishes, according to
one's own standards.

As a professional, the implication is that if you don't do a good job,
you won't get paid. Mind you, more than one person has paid another to
do a job and had a poor result. So, in the individual instances,
professional is no guarantee of quality. However, in the long run, an
incompetent professional will starve. And, if it's an activity for
which professional licensing is required (Engineer, Doctor, Lawyer,
Accountant, etc.), there's more requirements.

> have it look nice too...
>

Stated that way, it should be possible to create a patch antenna that
has comparable performance.

Or a "patch looking" antenna.

There's a couple ways to go about it, none of which involve starting
with a 2.4 GHz patch operated at 1/20th the design frequency.

1) use something as a dielectric that has a high epsilon, so the
wavelength is shorter. For cellphones and the like, various ceramics
like alumina are used. It's pretty easy to get to epsilon=10, but that
only gets you to 1/3 the size.

2) build something like a meander line on a suitable substrate. This is
sort of the squashed flat version of a rubber ducky loaded vertical.
Rather than making a 3d spiral which is a "radiating inductor" you do it
on a flat surface. It's a bit tricky because a simple back and forth in
a single plane won't radiate very well (the field from one meander
cancels the adjacent one). But a spiral might work.

3) low loss lumped loading components.

But, to return to your original 2.4GHz patch.. it's going to look like a
capacitor of some sort at 144 MHz. The feedline would probably do most
of the radiation.

I'm liking panel-type antennas that are on the order of, oh, say, 0.2\lambda
by 0.2\lamba by perhaps .05\lambda or less. So electrically small, but not
super-electrically small. :-)

Considering a dipole is 0.5 lambda by 0.01 lambda, getting a factor of 2.5 smaller is easy. (that is, you want 40cm by 40cm or so)

A simple short dipole with capacity hats and inductive loading will get you there quite nicely.

Imagine a "I" with the feedpoint at the middle, on a piece of FR-4 or G-10 (epsilon about 2). make it, say, 30x30 cm. You could also make the dipole diagonal across the square, and have the "capacity hats" be along the edge.

You could fool with NEC for a bit and get pretty close.

Or, do what I'd do.. get yourself a piece of suitable insulating substrate (a plastic cutting board or piece of acrylic window pane) and some copper foil tape. Lay it down, measure it with an antenna analyzer or similar, and start adjusting.

I've built more than one antenna like this using copper foil tape on paper or plastic sheets.

>sorry for my English I'm a French student

I got a warning

COLINEAR.NEC wavelength=0.345 mtr.

Warn.: volumes for Wires 6 (tag 6) and 7 (tag 7) are intersecting.

it was picking up a frequency of 1 millihertz as well maybe the diameter was being picked up as a
scale factor

However this ran (slowly) - I chose auto segmentation

GW 1 1 0 0.025 0.919 0 0.025 1 1.e-3
GW 2 1 0 0.025 1 0 0.035 1 1.e-3
GW 3 1 0 0.035 1 0 0.035 1.13 1.e-3
GW 4 1 0 0.035 1.13 0 0.025 1.13 1.e-3
GW 5 1 0 0.025 1.13 0 0.025 1.26 1.e-3
GW 6 1 0 0.035 1.26 0 0.035 1.3899 1.e-3
GW 7 1 0 0.035 1.39 0 0.025 1.39 1.e-3
GW 8 1 0 0.025 1.39 0 0.025 1.476 1.e-3
GE 0

```
EK
EX 0 4 1 0 1 0
GN 2 0 0 0 20 0.0303
FR 0 1 0 0 869 0
```

chose far field plot 5 degree or 1 degree steps - full pattern.

The pattern looked sensible. Gain of about 4.6dB at 55 degrees from horizontal.

Warning was still there.

When the antenna becomes small, connecting wires can become a significant -- if not the dominant -- part of the radiating structure. So some attention has to be paid to them, too. Consider a short end loaded dipole, with large capacity hats at the wire ends. That's what your "patch" would look like if fed from the center. And it's not a bad choice for an electrically small antenna. The radiating is done by the dipole wire, and the end plates serve to make the current uniform along the wire, raising the radiation resistance and improving the efficiency over a non-loaded dipole. If you move the "dipole" toward the outside, some uneven current will flow on the plates and they'll contribute to the radiation. NEC can do a good job of modeling these structures, with the plates modeled as wire grids, if some care is taken. Of course it can't handle dielectrics. Making a planar antenna on a dielectric material might be advantageous, but putting dielectric between the two halves as in a conventional patch would likely reduce the efficiency without providing any advantage.

What you'll be making is just another small antenna, with no special properties because of its resemblance to a properly functioning patch. So you have to deal with the same considerations you do with any small

antenna, all directed toward minimizing the I^2 * R loss.

when amateurs get bored out of their mind of the activity in question
they can take a break from it. Professionals cannot. They must
soldier on until they get interested in their livelihood again.

I believe that the "quitting (or resting) is not an option" is what
makes professionals so much better than amateurs in almost all cases.

Can there even be such a thing as an amateur soldier?

Was it a water based silcone sealant? I have observed high VSWR and noise on an antenna feed that used such, until the stuff had thoroughly dried / cured. It does not seem to be affected by rain since the initial cure.

If it was not a neutral cure silicone, perhaps there is something galvanic going on?

URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader
opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35
f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider
amending its charter, and permit limited simultaneous crossposting to
rec.radio.amateur.moderated and one other unmoderated
amateur-radio-related discussion newsgroup. We are currently trying
this on a temporary basis (90 days, through early July 2009), and adopt
it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently
listed in the latest version of the "List of Big Eight Newsgroups" which
is crossposted monthly to news.announce.newgroups, news.groups, and
news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those
that have been created consistent with the suggestions in "So You Want
to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either
"radio.amateur" or "ham-radio" in their names, including
uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved
newsgroups up-to-date. In case we have overlooked any, and a submission
is rejected in error as a result, the rejected submitter can E-mail us
at our administrative contact address (in the signature at the bottom of
this article, and the default Reply-To for the rejection message)
requesting that it be added, and that the article be approved. We may
still choose to reject articles crossposted to any alt.* newsgroup with
an inappropriate name, including obscene language, embedded
name-calling, or encouragement of unlawful conduct.

I pulled off my power panel in preparation to installing wiring to a new spa. It was a rats nest of professional, inspected wiring. I rewired the entire thing. And you can find a lot more "quality work" like this in a lot of houses.

The sub-par professionals who do this work are more likely to lose their jobs when the market goes south, and there just isn't any work for them at all.

But during his employment, I have no doubt that the guy who wired my house did it quickly and cheaply, and the quicker and cheaper made his boss all the happier.I also have no doubt that there are hundred of other houses he did exactly the same way. As for the person who did the electrical inspection, I'll not speculate.

But the idea that the free market will weed out the poor actors is a noble one but not true. The free market is looking for the cheapest, not the best.

Actually so-called "professionals" quit all the time -- and it usually comes down to a decision about money ("can we still expect to make money on this project?") -- rather than a more subjective, emotional consideration an amateur might give ("I gave this guy my word I'd get this working for him, and I'm going to soldier on even though it's now clear it'll take twice as long as I thought").

Software projects by "professionals" are quit all the time -- there's some shockingly low percentage of software projects that are ever actually finished (like, <25%). Even for hardware projects, at least for awhile Tektronix seemed to be quitting upwards of a quarter of all the projects they'd start.

It was normal sealant silicone from a diy store.

Usually a problem of poor specification. You cannot design what is
not described. Frequently, success is in the mind of the beholder:
"Oh! I forgot to mention you need to....(gestures made here). You
know what I mean."

In other words, professionalism that fails to rise above rank amateur.

My amateur designs are far more complete and robust than professional
ones, but they are not commercial. They would take too long the first
time (but they always could have been done in the time it had actually
taken to get to shipping).

Tracy Kidder's "Soul of a New Machine" proved how little so-called
professional effort is needed to do a professional job right. I work
with a lot of inventors/entrepreneurs whose idea-to-shipping time is
measured in the single digits of weeks.

What is "normal".

There are two kinds commonly available, neutral cure and acetic acid
cure. Some of the neutral cure ones are water based (ie water washup of
un-cured material).

If you use acetic acid cured silicone on metals, it corrodes them.
Silicone sealants intended for roofing will have a neutral cure.

Do you know what you used?

That may be true after decades of "public education" successes, but there was a time, in my lifetime, when the free market DID work because people were willing to pay for the best so as not to have to pay for "bargains" again and again. But then Toyotas and Hondas came along and the cheap bastard became a bigger market force than people with old fashioned outmoded values like doing a job right and making something to last.

actually, the market looks for "good enough"..

And, in the long enough run, it does weed out the poorer actors. Of
course, in a growing market(e.g. a housing boom), there's always room
for new incompetents to enter.

Pulling the plug on an IT project is not necessarily a bad thing. A
project I've been working on has changed functional scope four times
in the last nine months. Is it any wonder the project is six months
late?

WHOOSH - the sound of a deadline flying by.

Business owners and project managers are reluctant to make any
admission of poor decision making. Being able to say the project is
'done' is how too many measure success. User adoption and satisfaction
always seems to be secondary. Arbitrary due dates are determined
before any real analysis of the problem and potential solutions is
made. Requirements fall by the wayside as EOQ or the day after
Thanksgiving approaches. Project managers, especially the
non-technical, often fail to manage their own unrealistic
expectations. Over-promised and under-delivered is an unfortunate fact
of life.

>Usually a problem of poor specification. You cannot design what is
>not described. Frequently, success is in the mind of the beholder:
>"Oh! I forgot to mention you need to....(gestures made here). You
>know what I mean."
>
Absolutely. Deliver exactly what the customer asked for and then
they'll tell you what's missing. And again and again .... For web
applications it's not unusual to be given a 'design' of what it should
look like (image only, no mark-up) and a contradictory list of
commingled business rules, requirements. features and functionality.

>In other words, professionalism that fails to rise above rank amateur.
>
>My amateur designs are far more complete and robust than professional
>ones, but they are not commercial. They would take too long the first
>time (but they always could have been done in the time it had actually
>taken to get to shipping).

>
We always do throw-away proof of concepts to test and better understand both design and functionality. Essentially the project gets written twice. Producing a proper deliverable is much easier if you've done 'it' before. Too many people consider the investment in any code as being too valuable to be discarded. That's just plain wrong. A maintainable and extensible design is of the utmost importance.

>Tracy Kidder's "Soul of a New Machine" proved how little so-called
>professional effort is needed to do a professional job right. I work
>with a lot of inventors/entrepreneurs whose idea-to-shipping time is
>measured in the single digits of weeks.
>
Much depends upon the complexity of the problem, management's understanding of possible solutions, and the skillsets, abilities & dedication of the individuals involved. In DG's case a knowledgeable project manager was working with a team of not just any recent engineering graduates. Most of these were hired specifically for the project. For all the successes in some respects the project can be considered a failure.

Very seldom does a business owner or project manager ask "what's the best way to ..." because in their mind they already have determined what the only solution is. IT should be treated as vested peers rather than day laborers.

Thanks for the explanation. I didn't know that the did a neutral (water
based silicone).

The one that I have used is the acetic acid cured silicone.

Then it is corrosive on aluminium. The galvanic currents created may be
causing or contributing to your noise problem.

I would be removing the stuff, difficult as it is to do, but if it is in
contact with metal, it is not suited to your application.

I must admit art that your ability to spew bafflegab is improving.
that one could almost go on one of those parody videos that pop up on
april-1 every year. unfortunately i think you actually believe your
own rantings... that is fine with me, i always get a good chuckle out
of them, though i am sorry that you killed off the magical levitating
diamagnetic neutrinos in favor of a charge dumping transforming
lepton, maybe that will help you explain why my ferromagnetic antennas
still work.

Well let's say that anything metallic or insulator that can carry a
charge is capable of radiation. The problem is that some materials
retain some energy in terms of the hysteryses curve.Since Maxwell
wanted to account for all forces and yet a easily adaptable
formula he chose to encompass materials that did not retain applied
energy so that he could still account for all forces. As far as
Neutrinos are concerned they become unbound electrons after giving up
their accumulated charge to the Earth's core. When they are
accellerated in radiation they again carry a charge but this time the
charge carries applied information. One poster suggested that I stick
to the description of "particle" and I have done that.
so obviously requires a different name.

but the fields around the aluminum retain energy even without
hysteresis, and you have talked of eddy currents, those are another
form of stored energy in a material. if you use maxwell's equations
properly with the correct boundary conditions you can account for all
those effects. by using maxwell's equations plus ohm's law(to handle
lossy materials and the conversion of current to heat) you can also
account for all effects of lumped elements.

so now neutrinos mutate into electrons, i'm sure the cern guys are going to try to figure that one out... the transfer of charge and mass must be some effect of the big bang that they are simulating so maybe they'll be able to figure that one out. since neutrinos carry no charge or magnetic moment it would be rather hard to accelerate them, its damn hard to even slow them down since they interact very rarely with matter.

In the beginning, I was confused, then I read this on the internet.

"Radiators or antennas of present day follow the form of Yagi antennas
that are planar forms (parallel) at right angles to the center of
gravity of our Universe."

I wondered, how could antennas that look like this;

http://www.df9cy.de/tech-mat/zx6-6/2008-05-19_df9cy_all2.jpg

maintain their orientation with respect to the 'center of gravity of our
universe' as the earth spins in its axis and moves around the sun.

Since "Classical Physics" was mentioned I knew I had to take a more
classical view of things around me.

Aha, now I understand! The center of the earth must be the center of the
universe. That was the classical view of everything at one time.

But then. I saw antennas like these.

http://imghost1.indiamart.com/data2/LG/JV/HELLOTD-1801186/vhf_yagi-250x250.jpg
http://www.telonics.com/images/photos/rans4a_truckroof.jpg

They are not oriented the same.

Once again, I am confused.

On the other hand, Art may have wanted to make his post on Thursday.

(Apologies go to the owners of the pictures.)

Perhaps you can explain with specifics.

and you have talked of eddy currents, those are another
> form of stored energy in a material.
Maxwell accounted for those when he added displacement current
but he took it as an action not as stored energy since there is an
equal and oposite reaction which can be seen as skin reaction.
Thus a steel radiater versus one of aluminum will expend more energy
in penatrating the skin which detracts from energy that could be used
for radiation.

 if you use maxwell's equations
> properly with the correct boundary conditions you can account for all
> those effects. by using maxwell's equations plus ohm's law(to handle

> account for all effects of lumped elements.
Yes that is true but Maxwell and Heavyside were solely interested in
reducing
the number of laws that were in existent in those days. If you want to
backtrack and add a fresh law then you are on the right track and I
imagine you can expand them so the exceed the original number that
Heaviside had to deal with. You certainly have my support!

>
> so now neutrinos mutate into electrons,

The mass is the same, the differnce is the charge it carries.
The reasoning behind the mass content is that it is the smallest
possible mass such that the speed of light is a constant. At the same
time science has not determined for comparison the chemical make up
for all these different stages so we have to walk before we can run. A
case in point is the electron removed from a neucleus of a filiament
via the addition of heat to increase oscillation in a CRT. the
difference between such a electron
and the neutron/unbound electron has not been ascertained.

i'm sure the cern guys are
> going to try to figure that one out... the transfer of charge and mass
> must be some effect of the big bang that they are simulating so maybe
> they'll be able to figure that one out. since neutrinos carry no
> charge or magnetic moment

I don't think that is true as the mass is accelerated when it upsets
equilibrium around the Sun A similar action occures when impact
with Earth's polar fields occures where one often can see the effects
in a aurora when energy in the form of light is removed.

it would be rather hard to accelerate them,

> its damn hard to even slow them down since they interact very rarely
> with matter.

But they do have matter! Remove the charge that they carry removes
momentum.
We have millions of the floating around per cubic metre in the Earths
atmosphere looking for a place to rest such as a diamagnetic surface.

It is good to see you thinking outside of the box

Anyone know the velocity factor of JSC #1317 450 ohm line, 18 AWG?
Googling seems to give a variety of answers, and it's not posted at
the JSC site.

tnx,

Bob

Hi Bob,

If you were to find a specification, it stands every chance of being
wrong. How much wrong is wholly dependant on your need for accuracy.

The answer to your question can only be effectively found at the bench
through measurements. Various reports from different reporters will
reveal a range of values because test conditions are also very
important and their variety give considerable sway. Some variation is
simply due to poor measurement technique. Some variation is a
function of production variation. Weather will contribute a
significant variation - more for ribbon line than open line.

At the end of the day, you can take an average of all such reports and
simply buy into the proposition that you have to tolerate a certain
level of indeterminacy. If you application demands precise accuracy,
then you might find you will never achieve it.

What language is this?

Neutron is not the same as neutrino.
Mass of electron does not equal mass of neutrino.

I look forward to your specifics with respect to the above
Maybe point me towards the book that you authored where they compared
the mass
to each other? I am really interested in the comparison for future
notes.
Still, if that is the only thing that you are scratching your head on
I didn't do to bad.
I certainly knew that even with a rewrite spammers would still launch
missiles and you have always stood above the rest in the past.
Some children like to bully and some always stay as a child even when
they grow upwards.
Fortunately, some that bully are now going to prison.

Wes, N7WS, measured some Wireman lines similar to that above. His measurements indicated Zo quite different to nominal, and velocity factor around 0.9.

For applications where velocity factor is important, eg the 'matching section' of a G5RV, I suggest you measure the actual cable.

Wes's data is included in TLLC (http://www.vk1od.net/calc/tl/tllc.php). Your cable has similar stranding to Wireman 551, but velocity factor will depend on the detail of the dielectric extrusion and punching. If JSC is the manufacturer, they may even be the source of Wireman lines, in which case Wes's data may be directly applicable.

I have reservations about the adequacy of copper cladding on the cable such as yours at the lower end of HF.

Owen

I'm plugging the velocity factor figure into Cecil's program for
optimum feedline lengths on a multiband dipole, IMAXMIN.EXE. Given the
approximate nature of this kind of feed, a ballpark figure is probably
okay.

Hello Bob,

I used the ATLC program to calculate the properties of weird transmission lines. It accepts arbitrary shaped dielectric material. It outputs the line properties. When you run two simulations (with window and without window), you can average them to find the velocity factor of the ladder line.

The program can be retrieved from atlc.sourceforge.net (also Windows versions). When you hit the tutorial button, you can check whether it is worth to spend the time.

Looking to the picture of the line, most important for Zo is the ratio (bare wire diameter)/(wire + insulation diameter) as E-field is highest close to the conductors. For a ballpark calculation, I would use VF = 0.92.

You can also determine the quarter wave resonance length by measurement and calculate the velocity factor, but then you need several meters at hand. When you really need VF with high accuracy, measuring is the best option (around the frequency of interest). As the separation of the wires is very small (w.r.t. length), it is probably not necessary to correct for fringing at the open end.

Maybe the vendor cannot guarantee VF, because he receives material from different sources.

Best regards and good luck with determining VF,

Wim

I have often wondered the same thing. Mainly does the LMR400 center conductor have enough copper over the center conductor for 1.8 to 7 MHz. I don't use it at all as I just don't like the cladded cable.

The issue is greater with the CCS conductors in ladder line, because the
strands are thinner in the first place, and the core is steel.

The effect of CCS inner conductor in some types of RG6 shows up as a
departure from the classic loss model at frequencies below 5MHz.

Well, I discarded that idea because I have no idea how.

But then, on a hunch, I checked the manual that came with my MFJ-269,
and sure enough, on page 34, it tells how to measure Velocity Factor,
utilizing the distance to fault mode. It'll take a day or so to
recharge the 269's batteries, and then I'll have at it.

I don't suck people in , people just want to show off their phseudo
abilities because they have read a book. But all things are not in the
books. Look at those particles that settle on diamagnetic materials
such as water. They are so greedy for space to occupy that they can
scoop up water into droplets to maximize the surface area. Just
imagine if they did not rest on diamagnetic surfaces insects that walk
on the surface of these tightly clinging particles would fall into the
water! And how do you think that moisture rises in a updraft?
Because the water is in fine droplets covered by these particles.
Ofcourse if the droplets
go very high the water turns into ice leaving no diamagnetic surface
to cling to, so they are forced to take their charge to a nearby cloud
which esentially gets saturated and the charge carrying particles rush
to the ground. And we all know what happens when a charge is
accelerated
You know that once you accept the existence of these particles and the
predominating diamagnetic surfaces on Earth it begins to explain a lot
with respect to weather and tornadoes e.t.c. and why water circulates
when draining. It all come back to two forces,
direct and rotational which is the mechanism for radiation and the
laws of equilibrium otherwise known as boundary laws based on Newton.
Computer programs show that when skin depth is zero radiation is a
maximum because all the applied current is concentrated within the
encapsulating particles and none is flowing
in the base element. Yes, E=IR even tho there is no resistance
created by the element.
Now you have something more to complain about. Isn't physics wonderful?

Unfortunately, it's not really simple to make measurements with symmetrical line. You'll be exciting a common mode current which will travel with a different velocity factor and affect the measurement. I suggest making an approximate measurement, then doing final adjustments of the MFJ kept as far as possible from conductive objects including yourself. You'll have to adjust it, let go, back off and read the meter, readjust, etc. And then it'll still be a bit off unless the length of the MFJ meter is quite short relative to a wavelength. You'll also have to keep the line well away from any conductors and avoid coiling it. Of course, the same problems will exist when you install the line in whatever system it'll be used for, unless you can get it very well balanced.

It'll be a good exercise in learning some basic measurement techniques. Whether your results are adequately accurate depends on the application you'll be using the line for.

I sometimes taught a class on TDR techniques, and I'd start by connecting a foot or so of two-conductor ribbon cable -- just soldered into and to the shell of an SMA connector -- to a high speed TDR. The trace would show the large reflection from the open end, of course, but a smaller reflection seemingly coming from a point about 1/4 of the way from the end. I explained that ribbon cable isn't controlled for impedance, so it obviously had a construction anomaly at that point, and pinched the line, running my fingers along until the reflection from the fingers was at the same point as the anomaly. Then I cut the line well toward the TDR unit, discarding the portion with the anomaly. When the audience saw the *new* reflection about 1/4 of the way from the end of the shorter wire, I had their attention. And thus began a discussion of differential and common mode waves.

Yes, given all the variables, adjusting the final length, sometimes by
a few feet (depending on wavelength) is almost always required to
achieve system resonance. Remember that this approach is designed to
eliminate the tuner and therefore eliminate tuner losses and it is
designed to be used with a 1:1 current-choke-balun. Owen's comments
are certainly valid for systems using antenna tuners and 4:1 baluns.
In fact, if one chooses a ladder-line length halfway in between my
"good" (current maximum) and "bad" (voltage maximum) lengths, one will
obtain the odd 1/8 wavelengths points that are recommended for use
with 4:1 baluns. Those points result in a ballpark impedance in the
neighborhood of Z0 +/- jZ0/4, e.g. 400+j100 ohms. For those who
understand a Smith Chart, a picture is worth a thousand words.

Hello Richard,

Maybe he mends the displacement of charge via polarization that is accounted for in the epsilon of a material. This additional displacement current (with respect to the displacement current due to vacuum) does radiate as you know.

The more I look at it, the odd 1/8 wavelengths is probably the way I
will go, connecting to my tuner's 4:1 balun. There will be a 130 foot
flat-top, and the 450-ohm feedline length can be somewhere between 50
to 100 feet or so. Tnx for the input!

Correct, but he knew that.He was just spamming.His point was with
breakdown it is no longer a conductor. sheeesh

As an aside Planke hypothosized that light was a matter of packets or
quanta in sequence.
If one looks at the current and field drawing on my page you can see
that this is shown by the presence of only a single field intersecting
the eddy flow where as the other field does not. He inferred that the
flow was also segmented within the packet but I have seen nothing that
points to that. Either way, my page is in line with Planks thoughts
and completes another sement to the jigsaw.

He might agree, but he wouldn't know what you mean - even I don't.

There are only 6 words in a simple statement to examine here. Your
36+ words to explain that statement violate Occam's razor. Your
sentence above begs several paragraphs of untwisting.

Carrying a charge is unambiguous in the context of physics. That an
insulator performs this action plunges the original statement into an
abyss of ambiguity through redefinition of a word's accepted usages.

>This additional
>displacement current (with respect to the displacement current due to

This would make capacitors radiators. This generalism faces bleak
prospects in communicating a concept.

I guess then that you didn't look at the article I quoted.

Typical T match ATU's are lossier on capacitive loads than on inductive loads.

The odd eighth wave rule of thumb is a popular one. But, alternate odd eight waves (on a resonant load) assures the highest ATU losses for the given SWR.

These rules of thumb, and there are plenty that are conflicting, are usually given without explanation of why they work. We are a gullible lot!

The same occurs with 4:1 voltage tuner baluns which anecdotal evidence suggests assist match of a wider range of loads. There is good reason to think that the mechanism behind this is that their own loss assists, and it is an inefficient work-around for another problem.

Actually, I did look at the article.

It mentioned the voltage maximum problems, the current maximum
problems, and then said, "Is there a better option?" And I don't
understand the few sentences that follow that query. In other words, I
don't understand the solution -- i.e. "line lengths around 135
degrees longer than voltage maximum" :-)

I'll take a shot..

The VF, to a first order, depends on the dielectric constant (permittivity) of the medium separating the conductors of the transmission line. (more correctly, the medium containing the electric and magnetic fields) For differential mode, it's the insulation between the wires (for window line, a value somewhere between that of the plastic and that of air)...

For common mode, it's more the two wires acting as one conductor against the surroundings (e.g. earth) as the other conductor. The permittivity of that tends to be lower than that of the medium between the wires, so the velocity factor is "faster" for the common mode than the differential mode.

It's not quite that simple, of course, because the field surrounds the conductors in all directions, not just conveniently between them.

Another way to look at it is think of a balanced pair with distributed L and C suspended above a ground plane. The C (per unit length) between the pair is different than the C to ground, as is the L, for the common mode vs differential mode.

The location of voltage maxima depends on the load on the line. If you were to plot the impedance at various lengths of line, it is highest (and purely resistive) when fed at a voltage maximum. As the line is lengthed, that impedance becomes capacitive, and lower, eventually becoming lowest (purely resistive again) at the current maximum (90° longer than the point of voltage maximum). Increasing the length further, impedance becomes inductive and increases eventually becoming highest at the next voltage maximum. At a point of about 135° longer than the voltage maximum, the impedance presented to the T match is in the region where it is most efficient. Alternatively, you could state this as 45° shorter than a voltage maximum.

This is not your odd eighth wave (from a resonant load) rule, because
that also encourages the capacitive region where losses are higher.

Owen

Sure.

First, a balanced line, whether it's twinlead or coax, doesn't have any common mode current, by definition -- the lack of common mode is what makes it balanced. We're talking about a physically symmetrical line.

Whenever you have a two conductor line, you effectively have two transmission lines, differential mode and common mode. Although you actually have only one current on each conductor, by taking advantage of the principle of superposition you can mathematically separate the two currents into two *sets* or components of currents, analyze their effects separately to gain a better understanding, and simply add the results if you want to know the overall solution. The sum of the common mode and differential currents are the actual conductor currents, and the sum of the common mode and differential responses is the actual response.

The differential or transmission line mode waves (voltage and current) are the components which are equal and opposite on the two conductors, so the field is strongest between the two conductors, fringing outward in the case of ladder line. The presence of the dielectric material in a major portion of the field slows down the waves, lowering the velocity factor. In the case of coax, the field is entirely within the dielectric so we can easily calculate the velocity factor if we know the dielectric constant of the material. In the case of ladder line, we don't know what fraction of the field is in the air and what's in the dielectric without a very advanced computer program, so we have to measure the velocity factor. The fraction and therefore velocity factor changes, by the way, with frequency, a phenomenon known as dispersion.

The common or antenna mode waves are the components that are equal and in the same direction or polarity on the two conductors. The field is the same as it would be if the two conductors were connected together to make a single conductor. One conductor of the common mode transmission line is the two conductors of the ladder line, and the other is the Earth and/or surrounding conductors. These two common mode transmission line conductors are usually much farther apart than the ladder line conductors, so the common mode characteristic impedance is higher than the differential mode impedance. The velocity factor is usually higher, too, because the field is between the two common mode conductors -- the ladder line and the Earth --, and almost none of it is in the line

dielectric. So its velocity factor is nearly 1. In my TDR demonstration, the common mode open end reflection occurred before the larger differential mode reflection because of the higher velocity factor, so it looked like a differential mode reflection from a point short of the end. (And I helped reinforce this mistake in order to get the audience's attention.)

Any two conductor line supports both modes and behave the same, but coax is a little easier to understand because the differential and common mode currents are actually physically separate -- so no mathematical hocus-pocus is necessary. The differential currents and waves are entirely inside the cable, and the common mode currents and waves are outside. The velocity factor inside (differential mode) is determined by the dielectric material, and the velocity factor of the outside (common mode) is nearly 1.

of course insulators can 'carry' a charge, they just aren't very good
at getting it from point a to point b. ever rub a balloon and stick
it to a wall? both are decent insulators yet there is obviously
charge at work. ever comb your hair with a rubber comb and see your
hair stand up? charges being 'carried' on insulators.

Yes you are correct Dave but that has its advantages. At a later age
especially when you are retired you are not concerned with exams
coming up and cramming. You have time to study and even question what
you read. So I took up the hobby of ham radio and because of my
background I went thru various phases including improved mixers and
the like and eventually very large antennas or long boom antennas, all
the way upto 80 foot long by following Lawson. Then I changed to small
antennas and ofcourse the reading that goes with it. No, I am not a
"electrical" engineer but nor are most hams, so yes in a way I am self
taught. This is probably why I pursued the Gauss approach where
experimenters did not give it a passing thought because of prior
teachings. Thus it would not be unusual to find yourself working and

thinking outside the box. Remember it is a hobby that includes people from all aspects of life, and they should not be detracted from the hobby by those who feel they are better suited to understand all that goes with ham radio. So yes, by not following a structured education on antennas I am bound to make a lot of mistakes but it also allows me to go off track to areas that were discouraged by formal teachings. Some times the one eyed man becomes king especially when his earlier life it was drummed into him the overiding importance of equilibrium in Newtons teachings which all mechanical engineers absorb from the beginning.,
As far as Chip was concerned he followed a similar thinking where all his antennas were in equilibrium or balanced in a two dimensional form. So he is building efficient antennas with respect to area used where the radiation is judged on its final aperture. He is in fact following the cardinal rule of equilibrium even thohe suffered from the "not invented here"
syndrome where all is upposedly known by opposing experts.

As Roy has explained, you need to stop common mode current from
significantly altering your measurement.

I have had sucess with placing a balun of a string of ferrite cores over
the line. It is easy to observe the effectiveness using a VNA sweep, a
bit tricker with the MFJ269.

I have also found that stretching the line out straight causes the worst
common mode problems, but if you coil it, you have to keep adjacent turns
much further apart than the line's conductor separation.

All this has to be done with the line suspended in the air, well clear of
other dielectrics or conductors. (Hint: fishing line can be your friend!)

Before these analysers, we measured the resonant frequency of a line
section using a GDO. By very loosely coupling the GDO, and reading the
GDO frequency from a calibrated receiver, good results could be obtained.

I do have a W2DU-style balun of ferrite beads on coax, if that is what
you mean.

I also have an MFJ gizmo, a tiny 1:1 current balun for antenna
analyzers, a coax fitting on one side, and balanced line fasteners on
the other side -- but I'm guessing then I'd be measuring the velocity
factor of the balun, in addition to the balanced line.

That means literally threading some suitable ferrite toroidal cores over
the transmission line you are measuring.

If you add a separate balun between the analyser and the cable under test,
you introduce an unknown component that will probably disturb your
readings.

(Drum-roll) tada-boom.

So, Toto, we are not in Kansas anymore. Here in Odz, insulators AND conductors can BOTH carry a charge.

[Glancing at the bottom of the house they traveled in through the Twister. Two legs are exposed.]

Look! Under the porch! Apparently those ruby slippers cannot carry a house.

[Munchkin] You must see the Professor of Odz - follow the yellow brick transit line.

Toto, do you think ruby slippers can carry a charge along the yellow brick transit line?

[Tin Woodman] Can I go with you Dorothy? Do you think the Professor of Odz can give me a diamagnetic heart?

[Scarecrow] And me! Don't forget me, Dorothy! I want the Professor of Odz to give me a patent so I can prove my intellect.

[Lion] Roawrrrrr! I'm going too so the Professor of Odz will grant me courage to stand up against newsgroup bullies.

[Toto] jest let me hump the leg of Glenda, the Witch of the West - her Tiara is ï¿½bercool.

Another question -- I'm thinking of cutting a 10-foot section of
balanced line to test. Should I count the bared pigtails of the line,
which I will attach to the analyzer's coax output, as part of the 10
foot length? Or just count that part of the line where all insulation
is in place?

Aha.. you start to see the problems in precision RF measurement... Where is the "reference plane"..and how do you calibrate out the "fixture".

One way to do it is to do two sets of measurements. Do one with your 10 foot length. Then, cut 5 feet off and do it again. Then, the "difference" between the measurements is the result for the now missing 5 feet.

How much precision are you looking for, anyway. To a first order, think about how long that fixture is. If it's an inch or so, that's less than 1% of the overall length of the line.

I think 10 feet is going to be too short to make a good measurement, because the lengths of such things as the pigtails and the MFJ are a substantial fraction of the overall length. I recommend using the whole length of line you have. You might have to be a bit creative in keeping it away from other conductors, but that'll give you the best results.

When you do make the measurement, maintain the integrity of the line to as close to the impedance meter as you can. Then measure the line to the impedance meter connector.

What you have is two transmission line sections in cascade, one with bare conductors, and one with the conductors immersed in insulation.

If you want to measure the effects only of the latter, you need to find some way of minimising the contribution of the former.

The calibration of the MFJ269 is not that flash that you will pick a mm or two. When I have used them for the test you are performing, I zip tie the conductor to the external threads of the connector so that there is as close to zero length of 'different' transmission line as possible. You could also use a small stainless hose clamp, but in my experience, the zip tie has been reliable.

You can zip tie a piece of PE irrigation pipe to the VFO knob so that you hand doesn't need to be within half a meter of the instrument, use a wooden table to support the instrument, use the balun I suggested, and arrange the line to minimise radiation from residual common mode current.

I would try to measure a length of 10m or so. It is a compromise between making end effects (tails, effect of the windows) insignificant, an effective balun, and physically supporting the line for least radiation and other external influences.

Some of my focus was on trying to get a valid measure of R as well as X, R due to line losses alone.

I have 53-foot- and 122-foot-long lengths of the line. I might stretch
the 53-footer from the roof out toward the back fench, and measure
that.

Thankyou, Jim & Roy.
Your explanations were most enlightening. I just couldn't get my head around the "how & why" the VF should be different. I have also realised why I have sometimes seen more than one TDR reflection from a perfectly good transmission line.

1087. Measured Velocity Factor of balanced line

Newsgroup: rec.radio.amateur.antenna

Thanks to all for the advice on measuring velocity factor.

I suspended 53.25 feet of JSC #1317 18-AWG balanced line in the backyard.

At a velocity factor of 1, the MFJ 269 claimed an electrical length of 59.5 feet, which would give an actual velocity factor of .89.

After four or five more tries, I nearly replicated it with an electrical length of 59.6 feet.

To verify the results, I tried entering the .89 velocity factor to get the length of the line, and it kept coming in at a 26.6 foot length -- oh, well.

That sounds pretty close to half of the physical line length you
mentioned.

"Oh, well" means you didn't understand something, a problem to be resolved.

It is a long time since I used one of these.

I assume you are using the Distance to Fault mode.

Did you find the first X=0 point to be around 4MHz? If you mistakenly found
the first at a higher frequency, it will give a harmonically related
result.

Owen
